Abstract

Many histerid beetles are necrophilous on carrion during both active and advanced stages of decomposition. In this study, 13 species of *Saprinus* were recorded on carrion from Lebanon, containing eight that are new for the Lebanese fauna. The following *Saprinus* species are newly recorded from Lebanon: 1) *Saprinus* (*S.* caerulescens caerulescens) (Hoffmann, 1803); 2) *S.* (*S.* calatavensis Fuente, 1899; 3) *S.* (*S.* chaetites (Illiger, 1807); 4) *S.* (*S.* godet (Brullé, 1832); 5) *S.* (*S.* maculatus (P. Rossi, 1792); 6) *S.* (*S.* strigil Marseul, 1855; 7) *S.* (*S.* submarginatus J. Sahlberg, 1913; and 8) *S.* (*S.* tenuistris sparsutus Solsky, 1876. The peak activity was recorded, key for the species is provided, and habitus images and male genitalia are illustrated in order to facilitate their taxonomic identifications. *Saprinus* species are diverse and common on animal carcass; they were likewise collected from a human cadaver in Lebanon. Preliminary comments on biology and distribution of the studied species are given. Our paper represents the first faunistic study on Histeridae from Lebanon. A rigorous research program regarding the biology of *Saprinus* in Lebanon and the neighbouring countries would greatly improve the knowledge of the diversity, activity, and possible forensic value of *Saprinus*.

Carrion, key to species, Lebanon, peak activity, Saprinus

Introduction

Coleoptera (beetles) have proven to be useful in forensic investigations when fly larvae cannot be obtained or when they left the carcass and only beetles could be sampled (Zanetti et al. 2015). When examining the faunal succession of beetles on carcasses, the carrion beetles (Silphidae) are the first to be attracted, followed by the rove beetles (Staphylinidae) and clown beetles (Histeridae) (Su et al. 2013). Histerid beetles have received rather more attention in both ecological and taxonomic studies (three world catalogues published in the last 40 years, numerous revisions; for the references see Lackner et al. 2015). Regarding their presence on carrion, Histerids have been reported as the second after the Staphylinidae in the number of species on carrion during both the active and advanced stages of decomposition (Majka 2008; Su et al. 2013). Within the carrion community, histerid adults are regular visitors and they have been mentioned in forensic studies that use decomposing pig carcasses as experimental models as well as in real cases on human corpses (Bajerlein et al. 2011; Aballay et al. 2013). Histerids prey predominantly on dipteran eggs and larvae, though certain members of this family were also reported as predators on other beetles’ larvae and even to practice cannibalism at low preferred prey densities (Byrd and Castner 2000; Kovarik and Caterino 2016).

Histerids are unusual among beetles in having just two larval instars. In the first instar the head capsule and sclerites harden and the larva becomes capable of killing and feeding on soft-bodied insects. Mandibles and terminal palpal segments darken and become visible through the egg chorion just before eclosion (Kovarik and Caterino 2016). They undergo complete metamorphosis and their larvae are predacious and feed on insect immature stages. The average development of this family from egg to adult is 20 days at 30 °C (Fakoorziba et al. 2017). Our study focused on adults of Saprinus and immature stages were unfortunately not collected, albeit we admit that their presence might be informative for the determination of the post-mortem interval. Based on our data collected from pig carcasses, autopsies, and field trips, Saprinus species were the most common and diverse within the histerids. This paper aims to clarify the diversity, abundance, and association of Saprinus species with decomposing carcasses in Lebanon.

In the Palaearctic Region, 357 species of the Saprininae subfamily have been reported so far (Lackner et al. 2015). With 116 species, members of the genus Saprinus Erichson, 1834 are the most numerous. Regarding the countries neighbouring Lebanon, 47 species of the Saprininae are known from Syria, with 29 species recorded from Israel (Lackner et al. 2015). Among Saprininae, Saprinus species show similar relative diversities (Syria: 26 species; Israel: 18 species). Lebanon, with only 11 species of reported Saprininae, is the poorest of the three countries. Hitherto, only 5 species attributed to the genus Saprinus: S. (S.) aegialius Reitter, 1884; S. (S.) magnoguttatus Reichardt, 1926; S. (S.) prasinus prasinus Erichson, 1834; S. (S.) robustus Krás, 1944.
Contribution to the knowledge of Saprinus Erichson, 1834...

(=S. (S.) vermiculatus Dahlgren, 1964) and S. (S.) subnitescens Bickhardt, 1909 have been confirmed from Lebanon (Lackner et al. 2015). In Lebanon, there is a dearth of faunistic studies on Coleoptera in general, and Histeridae are no exception. In our present study, we focused on the Saprinus species that were collected from cadavers, and provide a key to identification of Saprinus from Lebanon.

Materials and methods

The majority of specimens were collected on a daily basis during the decomposition process (Table 1). They were collected from the soil under five pig carcasses and 14 pit-fall traps placed in their vicinity in addition to the sampling of two specimens during autopsy in Beirut, Beirut district, Beirut Governorate [33°53'N, 35°31'E] of a human body brought from Arsal, Baalbek-Hermel Governorate, Baalbek district [34°10'N, 36°25'E]. One pig carcass was placed exposed in each of the five different localities during different seasons (Fig. 1): 1) Badghan, Aley District, Mount Lebanon Governorate [33°46'4.24"N, 35°41'14.78"E] at an altitude of 1174 m during summer (June and July); 2) Fanar, Matn District, Mount Lebanon Governorate [33°52'44"N, 35°34'04"] at an altitude of 250 m during spring (March and April); 3) Deir El-Ahmar, Baalbek-Hermel Governorate, Baalbek District [34°7'30.96"N, 36°7'22.04"E], at an altitude of 1040 m during summer (July) 3) Naas, Bikfaya Matn District, Mount Lebanon Governorate [33°54'42.4"N, 35°40'32.7"E] at the altitude of 1090 m during spring (April and May); and 5) Hasbaya, Natabtieh Governorate, Hasbaya District [33°23'52.35"N, 35°41.6'6.59"E], at an altitude of 750 m (July and August). In addition, a single pig head was placed in Fanar during the autumn season (September and October) and specimens were collected from pitfall traps surrounding it on a daily basis to compare the diversity of Saprinus during different weather conditions. Specimens from Hammana, Baabda District, Mount Lebanon Governorate [33°50'N, 33°44'E] at an altitude 1200 m and Sin El-Fil, Matn District, Mount Lebanon Governorate [33°52'N 35°32'E] at an altitude of 50 m were manually collected during field trips. Insects’ activity on the pig carcasses was also reported during the night.

Four stages of decomposition were reported on the carcasses: 1) fresh stage; 2) bloat stage; 3) active decay stage; and, 4) advanced decay stage. Based on Matuszewski et al. (2010), the onset of the bloat stage was the first day when the inflation of the carcass was present. Before the inflation the carcass was considered fresh. The duration of the active decay was associated to the presence of Diptera larvae that fed on the carcasses. The onset of the advanced decay was assigned when Diptera larvae moved away to pupate, and soft tissues were absent on the carcasses (Table 1).

General observation and dissection were carried out using stereomicroscope Nikon SMZ1500. Without genital extraction, the males of Saprinus species can be usually recognized through the examination of the anterior tarsal setae, which are expanded and lamellate, whereas they are unexpanded and pointed in female. Often the males possess a longitudinal depression on the metaventral and occasionally also a single or two tiny tubercles on the apical metaventral margin. Male genitalia were

Figure 1. Abundance of Saprinus species in the localities of the present study.

First macerated in 10 % KOH solution for about 3 hours, cleared in 80 % ethanol and macerated in lactic acid with fuchsin, incubated at 60 °C for another 30 minutes, and subsequently cleared in 80 % ethanol and then observed in α-terpineol in a small dish. Digital photographs of male genitalia were taken by a Nikon 4500 Coolpix camera and edited in Adobe Photoshop CS5. Genitalia drawings based on the photographs or direct observations were produced with the aid of Hakuba klv-7000 light box. Habitus photographs were taken by F. Slamka (Bratislava, Slovakia). Specimens were measured with an ocular micrometre. Due to the lack of phylogenetic information regarding the genus Saprinus, the taxa in our present paper are arranged alphabetically. For the morphological terminology the reader is referred to Ōhara (1994) and especially Lackner (2010). The general distribution of Saprinus species is extrapolated from Mazur (2011). Whenever Mazur (2011) does not list a given
species from Lebanon, while Lackner et al. (2015) report it, we specifically mention it. Specimens were identified using the key of Kryzhanovskij and Reichardt (1976) as well as comparing them with reliably identified voucher specimens deposited in the collection of T. Lackner. All synonymies of species listed here are according to Lackner et al. (2015), with the exception of *Saprinus (S.) certus* Lewis, 1888, which was transferred from the synonymy with *S. (S.) chalcites* to the synonymy with *S. (S.) frontistrius* Marseul, 1885 and *Saprinus (S.) lindrothi* Dahlgren, 1968 that was synonymized with *Saprinus (S.) prasinus* Erichson, 1834 (Lackner and Leschen 2017).

**Results**

Our field experiments on pig cadavers in five localities across Lebanon (Fig. 1) resulted in four histerid genera: *Saprinus* Erichson, 1834 (85.52 %), *Margarinotus* Marseul, 1854 (14.08 %), *Atholus* C.G. Thompson, 1859 (0.27 %), and *Hypocacculus* Bickhardt, 1914 (0.13 %). We collected two species of *Margarinotus*: *Margarinotus (Promister) brunneus* (Fabricius, 1775) and *Margarinotus (Grammostethus) ruficornis* (Grimm, 1852); one species of *Atholus*: *Atholus duodecimstriatus duodecimstriatus* (Schrank, 1781); and one species of *Hypocacculus*: *Hypocacculus (Hypocacculus) metallescens* (Erichson, 1834). The most abundant and diverse was the genus *Saprinus* of which 13 species were reported. Out of these, eight species are herein reported as new for Lebanon: 1) *Saprinus (S.) caerulescens caerulescens* (Hoffmann, 1803); 2) *S. (S.) calatravensis* Fuente, 1899; 3) *S. (S.) chalcites* (Illiger, 1807); 4) *S. (S.) godet* (Brullé, 1832); 5) *S. (S.) maculatus* (P. Rossi, 1792); 6) *S. (S.) strigil* Marseul, 1855; 7) *S. (S.) submarginatus* J. Sahlberg, 1913; and 8) *S. (S.) tenuistrius sparsutus* Solsky, 1876. This paper analyses the diversity of necrophilous *Saprinus* spp. collected from Lebanon and establishes possible association with the decomposition stages, which could provide more clues for the determination of minimum post-mortem interval (PMI)\textsubscript{min}.

**Diagnosis of the genus Saprinus Erichson, 1834 from the Palaearctic region**

The monophyletic (based on the literature references as well as on the on-going molecular studies by T.L.) subfamily Saprininae Blanchard, 1845 is characterised by the presence of distinctive sensory apparatus situated inside their antennal clubs (for more details on this, as well as on the general diagnosis of the subfamily see Lackner 2010) and by the opened antennal cavities, not covered by prosternal ‘alae’. Among the Saprininae, the genus *Saprinus* comprises usually ovoid to elongate-oval metallic histerid beetles (although they can also be entirely black, or possess reddish or yellowish maculae on their elytra) of moderate to rather large size (2.50–10.00) for the family. From most other genera, members of *Saprinus* differ usually by widely interrupted frontal stria in the combination of absent prosternal foveae. For the extensive diagnosis of this genus see Lackner (2010).
**Saprinus** Erichson, 1834, of Lebanon known hitherto

1. **Saprinus (Saprinus) aegialius** Reitter, 1884  
   Fig. 2  
   = *Saprinus incognitus* Dahlgren, 1964  
   = *Saprinus therondi* Auzat, 1931

**Type locality.** Greece.  
**Distribution.** Slovakia, Southern Europe, Mediterranean subregion, Armenia, Iran (Mazur 2011). Reported from Lebanon by Lackner et al. (2015).  
**Biology.** The biology of *S. aegialius* is not adequately known, but the species is often found on carcasses. This species is often confused with *Saprinus immundus* (Gyllenhal, 1808), and it was absent from our sampling (therefore not shown on a distributional map).

2. **Saprinus (Saprinus) caerulescens caerulescens** (Hoffmann, 1803)  
   Figs 3, 82, 85a  
   *Hister caerulescens* Hoffmann, 1803  
   = *Hister semipunctatus* Fabricius, 1792  
   = *Saprinus chobauti* Auzat, 1926

**Type locality.** Germany: Baden-Württemberg.  
**Distribution.** Southern Europe, Mediterranean subregion, Portugal (including the Azores Archipelago), Cape Verde Islands, Central Asia, introduced to Peru (Mazur 2011). Newly reported from Lebanon (Fanar, Deir El-Ahmar, Badghan, Naas, Has-baya; Fig. 82).  
**Biology.** This species is found frequently on carrion, with a preference for larger carcasses (e.g., those of dogs, sheep, cattle, camels, etc. – T. Lackner pers. observ.). According to Kryzhanovskij and Reichardt (1976) *S. (S.) caerulescens caerulescens* was collected on rotten fish, where it preyed upon the beetles of the family Dermestidae. In our samples, we collected 47 specimens. *S. (S.) caerulescens caerulescens* was abundant during the active decay stage of carcass decomposition and coincides with the presence of Diptera larvae.  
**Comment.** This species has another subspecies *S. (S.) caerulescens punctisternus* Lewis, 1900 that occurs in China, Mongolia, Korean peninsula and Russian Far East (Mazur 2011).

3. **Saprinus (Saprinus) calatravensis** Fuente, 1899  
   Figs 4, 15, 16–24, 82, 85b  
   = *Saprinus angoranus* Bickhardt, 1911

**Type locality.** Spain.
Contribution to the knowledge of Saprinus Erichson, 1834...

Distribution. Mediterranean subregion, Arabian Peninsula, Central Asia (Mazur 2011). The distribution of this species is not sufficiently known due to its confusion with the morphologically similar species S. (S.) chalcites (Illiger, 1807) and, mainly S. georgicus Marseul, 1862. Newly reported from Lebanon (Deir El-Ahmar, Hasbaya; Fig. 82).

Biology. Saprinus calatravensis is found on small and medium-sized carrion. According to Kryzhanovskij and Reichardt (1976) it prefers xerophilous landscapes and sandy soils. During our sampling eight specimens were collected of this species.

4. Saprinus (Saprinus) chalcites (Illiger, 1807)

**Figure 4.** *Saprinus* (S.) *calatravensis* Fuente, 1899 habitus, dorsal view.
Figure 5. *Saprinus (S.) chalcites* (Illiger, 1807) habitus, dorsal view.

**Distribution.** Mediterranean subregion, Africa, Arabian Peninsula, Central Asia, India, Burma, Australia (Mazur 2011). Newly reported from Lebanon (Hasbaya, Fanar, Badghan, Deir El-Ahmar, Naas; Fig. 82).

**Biology.** *Saprinus chalcites* is a widespread flying predator found on carcasses, rotting vegetable substances, as well as in dung. According to Kryzhanovskij and Reichardt (1976), large numbers of this species have also been found on flowering Stink lily (*Dracunculus vulgaris* Schott, 1832). In our samples, we collected 129 specimens, most abundantly during the active decay stage. Several specimens were likewise collected during the advanced decay stage after the departure of Diptera larvae from the carcasses.

5. *Saprinus (Saprinus) godet* (Brullé, 1832)
Figs 6, 35–43, 82, 86b

*Hister godet* Brullé, 1832
= *Saprinus bitterensis* Marseul, 1862
= *Saprinus godetii* Marseul, 1857 [emendation]
= *Saprinus pseudolautus* Reitter, 1904

**Type locality.** Greece: Peloponnesus.
Figure 6. *Saprinus* (*S.*) *godet* (Brullé, 1832) habitus, dorsal view.

**Distribution.** Spain, Portugal, southern France, Turkey, Georgia, Kazakhstan, Turkmenistan, Saudi Arabia (Mazur 2011). Reported from Azerbaijan, Greece, Italy, Mongolia, Uzbekistan and southern Russia by Tishechkin and Lackner (2017). Newly reported from Lebanon (Fanar, Badghan, Deir El-Ahmar, Hasbaya, Sin El-Fil; Fig. 82). In our samples 19 specimens were collected.

**Biology.** Found on carrion (Kryzhanovskij and Reichardt 1976).

6. *Saprinus* (*Saprinus*) *maculatus* (P. Rossi, 1792)
Figs 7, 83

*Hister maculatus* P. Rossi, 1792
= *Saprinus obscuripennis* J. Müller, 1899
= *Hister personatus* Fischer von Waldheim, 1823
= *Saprinus pseudocruciata* Auzat, 1920

**Type locality.** Italy: Etrusca.

**Distribution.** Slovakia, Hungary, south Europe, Turkey, Georgia, Azerbaijan, Cyprus, Iraq, Iran, Turkmenistan, Kazakhstan, Afghanistan (Mazur 2011). Newly reported from Lebanon (Badghan; Fig. 83).

**Biology.** Found chiefly on cadavers, less commonly also in dung or human faeces (Kryzhanovskij and Reichardt 1976). In our samples a single specimen was collected.
7. *Saprinus* (*Saprinus*) *magnoguttatus* Reichardt, 1926
Figs 8, 83

**Type locality.** Iran.

**Distribution.** Turkey, Syria, Iraq, Azerbaijan, Lebanon (Mazur 2011).

**Biology.** Reichardt (1941) reports this species from Azerbaijan as an inhabitant of mountain steppes (500 m); several specimens were also collected by pitfall trapping. In our samples, we collected two specimens from a human corpse that was in the active decay stage (Fig. 83).

**Comment.** Lackner et al. (2015) wrongly attribute this species to G. Müller (1937).

8. *Saprinus* (*Saprinus*) *prasinus prasinus* Erichson, 1834
Figs 9, 83, 87a

= *Saprinus lindrothi* Dahlgren, 1968

**Type locality.** Syria.

**Distribution.** Italy: Sardinia, Greece: Crete, Bulgaria, Turkey, Armenia, Jordan (Mazur 2011). It is reported from Lebanon by Lackner et al. (2015). We collected this species from the following two localities, Fanar and Naas (Fig. 83).

**Biology.** Widespread and frequent East-Mediterranean species found mostly on carrion (Rozner 2010). In our samples, 29 specimens were collected.

**Comment.** *Saprinus prasinus* has another subspecies *S. (S.)* *prasinus aeneomicans* G. Müller, 1960 that occurs in neighbouring Israel and Syria (Lackner et al. 2015). According to Kryzhanovskij and Reichardt (1976) this subspecies differs from the nominate one by a distinct bronze hue of the dorsum.

9. *Saprinus* (*Saprinus*) *robustus* Krása, 1944
Figs 10, 44–52, 83, 87b

= *Saprinus vermiculatus* Dahlgren, 1964

**Type locality.** Turkey: Ankara.

**Distribution.** Greece: Crete, Turkey, Georgia, Syria, Lebanon (Mazur 2011). We report this species from the following two Lebanese localities: Deir El-Ahmar and Hasbaya (Fig. 83).

**Biology.** According to Anlaş et al. (2007) *S. (S.)* *robustus* is attracted to dung. In our samples, three specimens were collected.
Figure 7. *Saprinus* (*S.*) *maculatus* (P. Rossi, 1792) habitus, dorsal view.

Figure 8. *Saprinus* (*S.*) *magnoguttatus* Reichardt, 1926 habitus, dorsal view.
Figure 9. Saprinus (S.) prasinus prasinus Erichson, 1834 habitus, dorsal view.

Figure 10. Saprinus (S.) robustus Krása, 1944 habitus, dorsal view.
10. **Saprinus** (*Saprinus*) *strigil* Marseul, 1855  
Figs 11, 84, 88a

**Type locality.** Ethiopia.  
**Distribution.** East and central Africa, Saudi Arabia, Turkey, Cyprus, Malta, Syria, Israel (Mazur 2011). Newly reported from Lebanon (Hasbaya, Badghan, Fanar, Deir El-Ahmar, Naas; Fig. 84).  
**Biology.** Insufficiently known, according to our observations it is similar to its congeners. In our samples, we collected 149 specimens mainly during the active decay stage and several specimens in other stages of decomposition (Table 1).

11. **Saprinus** (*Saprinus*) *submarginatus* J. Sahlberg, 1913  
Figs 12, 53–62, 84

**Type locality.** Syria.  
**Distribution.** Algeria, Turkey, Israel, Armenia, Azerbaijan, Afghanistan, Iran (Mazur 2011). Newly reported from Lebanon (Badghan).  
**Biology.** According to Kryzhanovskij and Reichardt (1976), *S. submarginatus* is a typical inhabitant of xerophilous localities situated in higher elevations. During our sampling, a single specimen was collected. It was collected from altitude of 1174 m, during the summer season (June) from Badghan, Mount Lebanon where the rainfall average was 0 mm and the humidity 55.98 %, which would be in line with the above-mentioned observations of Kryzhanovskij and Reichardt (loc. cit.; Fig. 84).

12. **Saprinus** (*Saprinus*) *subnitescens* Bickhardt, 1909  
Figs 13, 63–72, 84, 88b

= **Saprinus fagniezi** Auzat, 1912  
= **Saprinus lecontei** Casey, 1916  
= **Saprinus meridionalis** Ihssen, 1949  
= **Saprinus simulans** J. Sahlberg, 1913

**Type locality.** Hungary, Romania.  
**Distribution.** Central and south Europe, North Africa, Spain (including Canary Islands), Portugal (including Madeira), Turkey, central Asia, introduced to north America (Mazur 2011). From Lebanon already reported by Lackner et al. (2015). We herein report this species from the following Lebanese localities: Fanar, Badghan, Naas, Deir El-Ahmar and Hammana (Fig 84).  
**Biology.** A typical free-living volant predator found on carrion as well as in dung. In our samples we collected 242 specimens. *Saprinus* (*S.*) *subnitescens* was the most abundant species on the carcasses during both the active and advanced stage of decomposition.
**Figure 11.** *Saprinus (S.) strigil* Marseul, 1855 habitus, dorsal view.

**Figure 12.** *Saprinus (S.) submarginatus* J. Sahlberg, 1913 habitus, dorsal view.

= *Saprinus brunnensis* A. Fleischer, 1883

**Type locality.** Uzbekistan.

**Distribution.** Central and South Europe, Central Asia, Mongolia, North China (Mazur 2011). Herein newly reported from Lebanon (Deir El-Ahmar, Hasbaya; Fig. 84).

**Biology.** This species is found predominantly on carcasses. During our sampling eight specimens were collected.

**Comment.** *S. (S.) tenuistrius* has another subspecies, the nominotypical *S. (S.) tenuistrius tenuistrius* Marseul, 1855, which is known from Egypt, north Africa, Ethiopia and Arabian Peninsula (Mazur 2011). According to Kryzhanovskij and Reichardt (1976) the nominotypical subspecies differs from the ssp. *sparsutus* by aciculate punctuation on the apical elytral half (the subspecies *sparsutus* lacks this aciculate punctuation).

Association of the *Saprinus* species with the decomposing pig carcasses

*Saprinus* (*S.*) *subnitescens* was collected during the sampling of the months March, April, May, June, July, August, and September. It was collected during three stages of decomposition; bloat, active decay and advanced decay. The maximum amount of specimens was observed during the advanced decay stage of the carcasses. This species was dominant (83 specimens) in Naas (Bikfaya) during spring season at the mean temperature of 16.4 °C. Specimens were collected during both active decay and advanced stages of decomposition from Naas, Badghan, and Fanar, and less frequently from Deir El-Ahmar and Hasbaya, respectively. Moreover, this species was also collected during the bloat stage of decomposition from Badghan (Fig. 88b).

*Saprinus* (*S.*) *strigil* was likewise collected during the sampling events of the months March, April, June, July, August, and September, with the maximum of 104 specimens collected in August from Hasbaya, when the mean temperature was 26.9 °C. The specimens were collected mainly during the active decay stage, less frequent during the advanced decay and minimally present during the bloat stages. Unlike *Saprinus* (*S.*) *subnitescens*, this species was rarely present in Naas. A few specimens were collected during the bloat stage from Badghan (Fig. 88a).
Figures 26–34. 26 *Saprinus* (*S.*.) *chalcites* (Illiger, 1807) male genitalia: 8th sternite and tergite, ventral view. 27 8th sternite and tergite, dorsal view. 28 8th sternite and tergite, lateral view. 29 9th + 10th tergites, dorsal view. 30 9th + 10th tergites, lateral view. 31 spiculum gastrale (9th sternite), ventral view. 32 spiculum gastrale (9th sternite), lateral view. 33 aedeagus, dorsal view. 34 aedeagus, lateral view.

*Saprinus* (*S.*) *chalcites* was collected during the sampling events of the months of April, June, July, August, September and October. In general, it was dominant during the active decay stage of the carcasses. Peak abundance of 76 specimens was collected in August from Hasbaya during bloat, active decay and advanced decay stages of pig carcass decomposition. Similar amounts were collected during the active and advanced decay stages from Badghan. More specimens were collected during active decay stage than during the advanced decay stage from Deir El-Ahmar. *S. (*S.*)* *chalcites* was present in Naas only during the advanced decay stage (Fig. 86a).

*Saprinus* (*S.*) *caeruleascens caeruleascens* was captured in March, April, June, July and August; a maximum of 17 specimens was collected during the spring season from
Fanar, when the mean weather temperature was 17.6 °C. In general, more specimens were collected during the active decay stages than those collected during the advanced decay ones. Similar amounts were collected during those stages from Badghan. It was collected during the decay stage mainly from Deir El-Ahmar and less frequently from Hasbaya. Regarding the locality Naas, this species was there found to be present mainly during the advanced stage of decomposition and less frequent during the active decay stage (Fig. 85a).

spiculum gastrale (9th sternite), lateral view

aedeagus, dorsal view

aedeagus, lateral view.

Saprinus (S.) prasinus prasinus – the peak of its abundance of 27 specimens was likewise in Fanar during spring (March and April). They were mainly captured during the active decay stage and found to be less numerous in the advanced decay stage. This species was likewise collected from Naas during same season during the advanced decay stage only (Fig. 87a).

Saprinus (S.) godet – the peak abundance of this species was in spring in Fanar. It is mainly present during the active decay stage of carcasses decomposition and in lesser numbers during the advanced decay stage. More specimens were collected during the
active decay stage than from the advanced decay stage from Fanar and Badghan. It was only present during the active decay stage in Deir El-Ahmar and during the advanced decay stage in Hasbaya (Fig. 86b).

Both *Saprinus (S.)* tenuistrius sparsutus and *Saprinus (S.)* calatravensis were collected in July – August. The former was only collected during the active decay stages of Deir El-Ahmar and Hasbaya. It was more abundant in the locality Deir El-Ahmar in July; the mean temperature was 29.7 °C. The latter was mainly present during the active decay stage and less frequently during the bloat and the advanced decay stages (Figs 85b, 89).

*Saprinus (S.)* robustus was collected from Fanar in March during the active decay stage only, and from Deir El-Ahmar in July during both the active and advanced decay stages. Only a single specimen of *Saprinus (S.)* submarginatus and of *Saprinus (S.)* maculatus, respectively, was collected during the summer season from one locality (Badghan); the mean temperature was 20 °C. A male and a female specimen of *Saprinus (S.)* magnoguttatus were collected from a human corpse that was infested by Diptera larvae (Fig. 87b).
Figures 54–62. 54 *Saprinus* (*S.*) *submarginatus* J. Sahlberg, 1913 male genitalia: 8th sternite and tergite, ventral view 55 8th sternite and tergite, dorsal view 56 8th sternite and tergite, lateral view 57 9th+10th tergites, dorsal view 58 9th+10th tergites, lateral view 59 spiculum gastrale (9th sternite), ventral view 60 spiculum gastrale (9th sternite), lateral view 61 aedeagus, dorsal view 62 aedeagus, lateral view.

Key to *Saprinus* Erichson, 1834 from Lebanon

This key includes only those species specifically recorded from Lebanon so far. For the *Saprinus* species found in the neighbouring countries (Israel, Palestine, Syria and Jordan), which are likely to occur also in Lebanon (see Lackner et al. 2015 for details), the reader is referred to the key of Kryzhanovskij and Reichardt (1976) that contains most or all of the possible Lebanese *Saprinus* species.
Contribution to the knowledge of Saprinus Erichson, 1834...

1. **Elytra bicolored (Fig. 7)**
   - At least the entire lateral elytral margin orange-red, usually most part of the elytral disk orange-red with only a short band along the elytral suture black (Fig. 7) .............................................
   - *Saprinus (S.) maculatus* (P. Rossi, 1790)

2. **At least the entire lateral elytral margin orange-red, usually most part of the elytral disk orange-red with only a short band along the elytral suture black (Fig. 7) .............................................
   - *Saprinus (S.) magnoguttatus* Reichardt, 1926

3. **Elytra unicolored, never with red macula (Fig. 2)**
   - *Saprinus (S.) caerulescens caerulescens* (Hoffman, 1803)

4. **Pronotal hypomeron setose, fourth dorsal elytral stria strongly reduced, often absent. A large, usually metallic species (PEL = 5.00–7.50 mm) (Fig. 3) ...........
   - *Saprinus (S.) strigil* Marseul, 1855

5. **Pronotal hypomeron asetose, fourth dorsal elytral stria usually not reduced, fully developed. Smaller species (PEL = 2.50–6.50 mm) .................
   - *Saprinus (S.) subnitescens* Bickhardt, 1909

6. **Pronotal depressions deep, third dorsal elytral stria usually strongly reduced, black species without metallic hue (Fig. 10), male with only shallowly depressed metaventrite; male terminalia: apex of 8th sternite (velum) with dense tiny setae, 8th sternite medially strongly sclerotized (Figs 44–52) ...........
   - *Saprinus (S.) robustus* Krása, 1944

7. **Elytra with variously dense punctuation, but punctures usually not aciculate or striolate (some specimens of *S. (S.) robustus* can have striolate punctures, but then the third dorsal elytral stria is always strongly reduced) (Fig. 2) ...........
   - *Saprinus (S.) prasinus prasinus* Erichson, 1834
Apices of prosternal striae divergent, but never laying on lateral sides of the pronotal process (Fig. 53); usually smaller species (PEL = 2.50–3.90 mm)........17

Pronotal depressions absent, pronotal disk medially with distinct punctation, humeral elytral stria confluent with inner subhumeral one creating a supplementary dorsal elytral stria parallel to first (Fig. 6); male terminalia: apices of 8th sternite with thin, dense brush of setae, medio-laterally with a bean-shaped setose sclerite, aedeagus strongly constricted before apex (Figs 35–43)................................................... Saprinus (S.) godet (Brullé, 1832)

Pronotal depressions present, pronotal disk medially with only scattered fine punctation (Fig. 14).................................................................................. 19

Entire elytral disk with punctation, punctures separated by twice or more their diameter, dorsal elytral striae thin, impunctate (Fig. 14), antennal club large, light-amber coloured; male terminalia: apices of 8th sternite with tiny triangular accessory sclerite furnished with micro-setae, aedeagus short and stout, not dilated apically (Figs 73–81)............................................................... Saprinus (S.) tenuistrius sparsutus Solsky, 1876

At least the area between united sutural and fourth elytral striae without punctation (or punctures microscopic), punctures of elytral disk separated usually by less than twice their diameter (Fig. 12), antennal club mediumsized, reddish-brown. The following species are usually only reliably identifiable based on their male terminalia.................................21

Apical margin of metaventrite of male without tubercles. Male terminalia: 8th sternite with two rows of brush-like setae: one situated approximately medially and another apically, aedeagus constricted before apex; apex rounded (Figs 54–62) (Fig. 12)...... Saprinus (S.) submarginatus J. Sahlberg, 1913

Apical margin of metaventrite of male with two distinct tubercles (Fig. 15)....23

Tubercles on the apical margin of metaventrite of male slightly removed from metaventral margin (Fig. 15). Dorsal elytral striae surpassing elytral half; male terminalia: 8th sternite with large setose velum (best seen especially from lateral view), apex of aedeagus rectangularly dilated, truncated (Figs 16–24) (Fig. 4)................................. Saprinus (S.) calatravensis Fuente, 1899

Tubercles situated almost on the very apical metaventral margin (Fig. 25); dorsal elytral striae usually not surpassing elytral half; male terminalia: 8th sternite without large setose velum, apex of aedeagus only slightly roundly dilated (Figs 26–34) (Fig. 5) ............. Saprinus (S.) chalcites (Illiger, 1807)

Discussion

In an experiment performed in Al-Baha Province (Kingdom of Saudi Arabia) Saprinus species were commonly found on rabbit carcasses during spring, summer, and autumn. In spring, they were found to be abundant during the active decay and the first two days of the dry decay stages. However, in autumn they were common rang-

Figures 64–72. 64 Saprinus (S.) subnitescens Bickhardt, 1909 male genitalia: 8th sternite and tergite, ventral view 65 8th sternite and tergite, dorsal view 66 8th sternite and tergite, lateral view 67 9th + 10th tergites, dorsal view 68 9th + 10th tergites, lateral view 69 spiculum gastrale (9th sternite), ventral view 70 spiculum gastrale (9th sternite), lateral view 71 aedeagus, dorsal view 72 aedeagus, lateral view.

advanced decay stages of decomposition, when the Diptera larvae are active and feeding on the carcasses, and were also recovered from the soil after the departure of Diptera larvae to pupate. Saprinus (S.) strigil, Saprinus (S.) subnitescens, Saprinus (S.) cala-
Figures 73–81. 73 Saprinus (S.) tenuistrius sparsutus Solsky, 1876 male genitalia: 8th sternite and tergite, ventral view 74 8th sternite and tergite, dorsal view 75 8th sternite and tergite, lateral view 76 9th + 10th tergites, dorsal view 77 9th + 10th tergites, lateral view 78 spiculum gastrale (9th sternite), ventral view 79 spiculum gastrale (9th sternite), lateral view 80 aedeagus, dorsal view 81 aedeagus, lateral view.

travensis, and Saprinus (S.) chalcites were present on the carcasses earlier, in the bloat stage in the summer season, whereas in the spring months (as observed in Fanar and Naas) the arrival of Saprinus on the carcass was during the active decay stage (Figs 85, 86, 87, 88). Our data suggest that the active decay stage was reached faster during the summer season than during the spring. The histerid beetles were frequent on all carcasses, but were found to be more diverse during the warm season rather than during autumn. According to our observations, histerids tend to stay in the soil underneath
Figure 82. Distribution of *S. (S.) caerulescens caerulescens*, *S. (S.) calatravensis*, *S. (S.) chalcites*, and *S. (S.) godet* in Lebanon.

the carcass during the day and become active during the night. Some are predacious not only on Diptera immature stages but also on the dermestid larvae (Byrd and Castner 2000). Moreover, necrophagous beetles such as Dermestidae are present during the end of the decay process while predators are attracted earlier during the decomposition process (Santos and Santos 2016). This could explain the presence of *Saprinus* during the advanced decay when the dermestids are active. However, the decrease in the abundance of *Saprinus* during the late stages of decomposition coincides with the increase of *Dermestes* immature stages. The other histerid specimens among the genera *Margarinotus*, *Atholus* and *Hypocacculus* were also reported during the decomposition process of the carcasses, but with lower abundance in comparison with *Saprinus*. Mar-
garinotus, Atholus as well as Hypocacculus are known to be attracted to carrion (Kovarik and Caterino 2016).

It is possible that different patterns of residency on carrion in Saprinus result from the differences in release patterns of the volatile organic compounds (VOCs) attracting them (Bajerlein et al. 2011). The decrease in the abundance in late decay stages could be due to the decrease in VOCs. In forensic entomology, Coleoptera is an order of great importance; however, the neglect of this order is due to difficulties regarding taxonomy or its role on the carrion (Almeida et al. 2015). Each biogeographic region has its specific carrion insect fauna (Santos and Santos 2016). Our survey shows the diversity of Saprinus in Lebanon, their feeding habits and peak abundances during the warm season in the country.
In the present study, 489 specimens of *Saprinus* were recorded, representing 13 species. Out of these, 8 are new records for the Lebanese fauna (Fig. 1). The main aim of this study was to monitor the activity of these beetles on cadavers and identify the species that can be used in later forensic investigations of the country. To ease the identifications, a key for the species is provided, accompanied with illustrations of habitus and male genitalia. More rigorous research concerning both taxonomic identification and the larval development should be conducted to clearly establish the importance of histerid beetles in criminal investigations.
