It is evident that the restrictive forms of the harvest production function impose severe constraints on the fishery manager. If the technology exhibits non-jointness-in-inputs the catch per unit effort of each species is technologically determined. This means that vessels are unable to respond to price signals conveyed through differential royalties on species, or to observe species quotas which are in proportions other than those determined by the technology. If there is input-output separability the species proportions will be unaffected by changes in the amount of fishing effort. The effect of these constraints will be to raise the cost of fishery management. Imposing a low TAC on an overexploited fishery may imply a relatively low harvest from a relatively unexploited fishery. Quotas which are enforced in different species proportions to those dictated by the harvest technology may result in dumping of catches of the relatively low quota species. Quotas or royalties which are tightly enforced may result in vessels withdrawing from the fishery. Fishery managers will need to make the appropriate trade-offs between sustainability and catchability and this will require information about technology.

## 3. MULTIPRODUCT STUDIES OF THE SOUTH WEST PACIFIC TUNA FISHERIES

Three studies are currently underway of multiproduct production technology in the South West Pacific tuna fishery. A study of the longline fishery in the North East portion of the Australian Fishing Zone, funded by the Australian Fishing Industry Research and Development Corporation, is being undertaken by Campbell and McIlgorm (1992a, 1992b). This study is part of a more comprehensive study by McIlgorm (forthcoming). The other two studies are of fisheries in Papua New Guinea's EEZ and are being undertaken by Campbell and Nicholl (1992a, 1992b). One study recently completed is of the tuna purse-seine fishery and the other in progress is of the longline fishery. Both studies are funded by the Australian Centre for International Agricultural Research (ACIAR).

*3.1 The Australian East Coast Tuna Longline Fishery*

### 3.1.1 Introduction

The fishery extends along the Australian east coast from Cape York in the north to Sydney in the south. The tuna fishery in this area is multi-species, with catches of yellowfin, albacore, bigeye, and billfishes, (black, blue and striped marlin and swordfish). The fishery has both foreign and domestic fleets. The Japanese catch in this area of the Australian Fishing Zone (AFZ) totalled approximately 6000 tonnes of all species in 1990. The fishery is primarily based on yellowfin tuna destined for the Japanese frozen sashimi tuna market. However the fishery also has significant catches of marlin and swordfish. Catch from the east coast fishery had a value of approximately 20 million Australian dollars in 1990. This is smaller than Australia's largest tuna fishery, Southern Bluefin tuna, which was worth 72.2 million dollars in 1990 (Geen, 1991).

During the 1980's smaller domestic vessels became involved in the inshore tuna fishery. The domestic vessels have aimed at supplying the more lucrative fresh Japanese sashimi market. The domestic fishers catch approximately 600 tonnes of yellowfin with a small by-catch of other species. In 1991 the domestic fishery was worth approximately 7 million dollars at first point of sale.

There is also an Australian recreational sports fishery operating from ports along the East coast. These big-game fishing vessels target marlin and billfish as well as yellowfin and albacore tuna.

### 3.1.2 Management

The Japanese have been longlining for tuna in the East Australian fishery since the mid 1950s. The Australian Fishing Zone was formed in 1979. Since extended fisheries jurisdiction, Japanese access has been managed by a combination of restricted areas, seasons and licencing agreements negotiated annually with the Australian Government. An agreed number of vessels pay access fees and have not been subject to any catch limits until the most recent negotiations for 1992.

The domestic fishery is managed by the East Coast Tuna Management Advisory Committee (ECTUNAMAC). Entry to the fishery is by licence, referred to as an endorsement. Developmental endorsements have been introduced in the hope of promoting further development of the fishery. The domestic vessels are only capable of fishing inshore. Since the late 1980s an area extending to 50 miles from the coast has been kept exclusively for domestic access.

### 3.1.3 The Research Project

Research into the future management of the fishery has been promoted by the ECTUNAMAC of the Australian Fisheries Service. Workshops promoting discussion of future management options have prompted research on the economics of the fishery (McIlgorm, 1990).

### 3.1.4 The Objectives of the Research Project

The objective of the project is to provide management with an economic analysis that will assist in future management of the east coast region. This takes account of :

i) The costs and returns of the Australian vessels in the domestic fishery ;

ii) The benefits to Australia from licensing the Japanese fleet compared to other arrangements ; and

iii) The interactions between inshore and offshore fisheries.

Resource rent in the fisheries is estimated and the following policy issues are addressed :

i) Access fees - what type of scheme is most appropriate ?

ii) The potential economic benefits of Australianisation ;

iii) Interactions between inshore and offshore fisheries.

### 3.1.5 Data

Detailed catch and effort data for Japanese and domestic fishing vessels were made available to the project by the Australian Fisheries Service, (AFS), now the Australian Fisheries Management Authority (AFMA). This was in the form of computer logbook records for Australian and Japanese vessels for the 1980-1990 period. Japanese market price data was also made available by AFS for the same period. Data quality in the years immediately following the establishment of the AFZ was judged to be poor and therefore the 1984-1989 period was chosen for analysis. Domestic tuna price data were obtained from the New South Wales Fish Marketing Authority. Prices for the fresh sashimi market in Japan were obtained from the Fortuna-Daito fishing company, New South Wales.

### 3.1.6 The Cost Study

The rapid development of the domestic fishery has been monitored by fisheries management. However there has not been an economic survey of costs and incomes in the domestic fishery. Under the present project research a survey of approximately 100 domestic fishers was undertaken. This involved fieldwork along the east coast area. The results of the survey will be published in Campbell and McIlgorm, (1992). The methodology and detailed results can be seen in McIlgorm, (in prep). The domestic cost survey and logbook information were used to calculate the cost of effort for the domestic fishery. Estimates of the economic cost and profitability of the world-wide activities of the Japanese longline tuna fleet are reported in Campbell and Nicholl (1991). The cost of effort for the Japanese fleet in the east Australian area has been calculated by using the information reported in Campbell and Nicholl's study.

### 3.1.7 Multi Species Production

The fishery has not hitherto been subject to an examination of the economics of multispecies production, although targeting by Japanese vessels has been recognised as an issue in biological research (Ward et al., 1991). A dual revenue function approach is used to estimate the production technology in the fishery (McIlgorm, in prep). Results and policy implications of multi-species production are reported in Campbell and McIlgorm, (1992b).

### 3.1.8 Rent

To date there has been one attempt to calculate potential access fee levels in the fishery (Brown and Dann, 1991). This study used the approach developed by Geen (1990) and did not account for the possibility of multispecies joint production in the fishery.

The dual revenue function approach to production can be used to estimate potential rent from the Japanese fishery. The effect of access charges or royalties on the harvest of the various species will depend on the nature of the harvest technology. An understanding of joint production behaviour will contribute to the management of the fishery, particularly where restrictions on the catch of different species may be envisaged. Campbell and McIlgorm, (1992b) reports results of a spatial or zonal approach to production and rent calculation. Details of the estimation of spatial or zonal production can be found in McIlgorm (in prep.).

### 3.1.9 Future Policy and Foreign Fishing

In reviewing the management of the fishery McIlgorm (1990) concluded that management had managed the foreign fishery offshore and the domestic fishery as two separate entities. Given the likelihood that the fisheries are based on the same stocks it is evident that management policy should address both fisheries.

The foreign fishery has been managed by access to permitted zones. Through the 1980s the domestic fishery has increased the area reserved for Australian vessels to 50 miles from shore. The Japanese have been displaced from the

innermost coastal zone. However, the boundary between zones has not been subject to an economic assessment of potential economic benefits to Australia. Similarly, the cost to the Japanese of being displaced from these areas has not been specifically addressed. Quantification of economic benefits will assist in answering these questions. It is hoped that this research may have benefits for the general analysis of foreign fishing issues.

### *3.2 The Tuna Purse Seine and Longline Fisheries in Papua New Guinea's EEZ*

#### 3.2.1 Introduction

The tuna industry of the Western Pacific provides an important source of income for fishing fleets of a number of nations and island states which sell access rights to the stocks which are exploited from their EEZs. The size and potential value of the fisheries is such that management regimes which control the level of exploitation and account for interactions and conflicts between the different fisheries within the industry are being developed. However, in order to design and implement regulatory frameworks which take account of the conflicts and overexploitation which may arise from an unregulated industry, an understanding of the biological and economic basis of production is required. A review of some of the relevant issues is provided in Campbell, Menz and Waugh (1989).

Within the region one of the most productive fishing grounds for both the longline and purse seine fisheries is Papua New Guinea's EEZ. Moreover, the fact that both these fisheries are multiproduct fisheries with a range of vessel types, sizes and nationalities, make the task of the policy maker a complicated one. Separate analyses of both these fisheries have been conducted in order to examine how possible restrictions placed on the activities of vessels in these fisheries may result in shifts in emphasis of effort within or between the fisheries and changes in the benefits arising from them. A lack of understanding about the objectives and technical constraints which govern the workings of a fishery can result in the introduction of regulatory measures which lead to inefficiencies and the dissipation of potential benefits.

The longline fishery in Papua New Guinea supplies high quality tunas to the Japanese sashimi market. The main species caught are yellowfin, big eye, albacore, swordfish and black, blue, and striped marlins. For much of the history of this fishery, the only vessels to operate within Papua New Guinea's EEZ have been those of the Japanese fleet although more recently, longliners from Korea and Taiwan have fished in Papua New Guinea waters. The Japanese fleet has been the largest to operate in the region. South Pacific Commission (SPC) records show that for the period covering the economic analysis of the Papua New Guinea longline fishery a total of 238 Japanese vessels were active at some point in time. There were only two other nationality of vessels which operated in Papua New Guinea for this period according to official records, Korean (3 vessels) and Taiwan (1 vessel). The Japanese vessels ranged in size from 59 GRT to 379 GRT, the Korean vessels 110 GRT to 424 GRT and the Taiwanese vessel was 95 GRT.

The purse seine fishery harvests skipjack and juvenile yellowfin which is supplied to the canning industry in the region. The main purse seine fleets active in Papua New Guinea's EEZ during the period investigated were the US fleet (26 vessels) and the Japanese fleet (51 vessels). Vessels of other nationality such as Korea and Taiwan also fished in the EEZ during the period. The US vessels ranged in size from 985 to 1,559 GRT, and the Japanese vessels ranged from 116 to 999 GRT.

#### 3.2.2 The Research Project

Both the purse seine and longline studies are based on an analysis of monthly catches by individual vessels. The period of analysis for the purse seine fishery is 1983-1987 when both U.S. and Japanese vessels were engaged in the fishery. The longline study analyses the catch returns of the Japanese fleet over the period 1979-1989.

In both studies vessels were assumed to act as revenue maximizers during their fishing trips within the EEZ. A dual revenue function was used to estimate the production technology. In the longline study, attention focussed on the degree to which species caught in the fishery were produced jointly, while in the purse seine study the focus of the investigation was on the ability of vessels to target juvenile yellowfin. The implications for purse seine yellowfin targeting are that it could lead to overexploitation of this species and could reduce the returns and therefore benefits derived from the longline fishery.

### 3.2.3 The Data

The data which were used to analyse the longline fishery were obtained from the SPC data based held at the Tuna and Billfish Assessment Programme. The data describe the daily catch and effort activity at the individual vessel level, giving detail of data, vessel name and identification, gross registered tonnage of the vessel, the duration of the particular fishing trip the vessel made for any observation, latitude and longitude at 12 :00 noon (which is around the end of the period of hauling in the line), the number of hooks for a given set and the number and average weight of albacore, yellowfin, bigeye, bluefin, marlin, swordfish and sailfish caught for a given set. The data are believed to be a fairly accurate account of longline fishing activity in the zone, at least for the Japanese fleet. Price data are from the FAO GLOBEFISH data base and are average monthly ex-vessel prices for all species mentioned above, for the Japanese port of Yaizu. Although all longline catch is not unloaded at Yaizu, these prices are widely regarded as representative of the tuna market situation in Japan.

The longline analysis was conducted using monthly vessel level data for the period 1979 to 1989. Daily observations on each vessel were aggregated to give monthly records of catch and fishing effort (measured as the number of hooks set) which together represent a cross-section of the longline fleet in any month and year. These monthly records of each vessel's fishing activity for the period of the analysis were then combined and used to estimate supply functions for each of the species harvested.

The data used in the purse seine analysis were very similar to that of the longline investigation : vessel level daily observations of fishing effort (size of vessel and number of sets), type of set (log or free-school) and catch records for the two main species of this fishery (skipjack and yellowfin). Yaizu monthly ex-vessel prices were used for the analysis of the fishing activity of the Japanese fleet and American Tuna Sellers' Association (ATSA) prices for the U.S. fleet. Daily vessel observations for the Japanese and U.S. fleets were aggregated to monthly observations on each vessel. The cross-section data for the period of the analysis (1983-1987) were used to estimate a supply function for each of the two species. No records of U.S. fleet activity prior to 1983 are evident and the access agreement between Japan and Papua New Guinea expired in March 1987 and has not been re-negotiated since.

### 3.2.4 The Cost Study

In recent studies, Campbell and Nicholl (1991, 1992a) analysed information published by Japan's Ministry of Agriculture, Forestry and Fisheries (MAFF) on the costs and returns of Japanese fishing vessels. They report the economic profit and return to invested fixed capital for the Japanese offshore and distant-water tuna fishing fleets for the fiscal years 1979-80 to 1988-89. The three gear types covered by this analysis are longline, pole and line and purse seine. The information provided for purse seiners is for group purse seine operations.

End of year financial data published by the Japanese Ministry of Agriculture, Forestry and Fisheries are used to calculate average annual per vessel operating profit. The opportunity cost of capital is calculated using estimates of the (annual average) required rate of return to Japanese capital over the period. Two estimates of the required rate of return are used. One is a basic measure evaluated on observed debt-equity ratios for a cross-section of Japanese firms. The other is an adjusted measure which reflects the prevalence of cross-holdings and subsidiary ownership amongst Japanese firms. Together with reported depreciation on fixed assets, these estimates of cost of capital are deducted from operating profit to give estimates of economic profitability. Operating profit less depreciation is calculated as a proportion of the fixed capital employed to give an actual rate of return to fixed capital which is then compared with the required rate of return over the period.

They also calculate the cost of fishing effort for the various categories of Japanese tuna vessels. A day fished is taken as a unit measure of fishing effort (searching and catching). The estimated average total cost per day of owning and operating a vessel type is adjusted by a factor which reflects implicit "support costs" (such as land preparation, steaming to and from fishing grounds, etc.) for a day fished to give the total cost per fishing day of different vessel types. This information can be used to gauge the expected costs of Japanese tuna vessels operating as distant-water fishing nation vessels in the EEZs of the Pacific Island States.

## 4. THE COST OF REDUCING PURSE SEINE CATCHES OF JUVENILE YELLOWFIN : AN APPLICATION OF THE MULTI-SPECIES APPROACH

Yellowfin tuna is an important species in both the purse seine and longline fisheries in the Pacific Islands Region. In 1984 yellowfin constituted 28 % by weight of the purse seine catch, and 37 % of the longline catch. Yellowfin is the only species which has an important role in both fisheries. The purse-seine fishery harvests juvenile yellowfin for canning whereas the longline fishery catches adult yellowfin for sashimi. Obviously there is a potential for the purse seine harvests to reduce the population, and hence the catch rates, of adult yellowfin. It may be in the interests of the Pacific Islands nations to attempt to reduce purse-seine juvenile yellowfin catches in order to increase the value of the longline fishery. Before a policy of reducing juvenile harvests is adopted some estimates of the economic costs and benefits are required. To estimate the costs imposed by the policy on the purse seine fishery, an estimate of the production function for that fishery is required. The production function is a two-product relationship, with skipjack tuna as the other product.

Campbell and Nicholl (1992a) examine the question of whether purse-seine vessels can "target" yellowfin tuna. By "targeting" is meant the ability to vary the proportion of yellowfin in the catch in response to relative price incentives. If targeting is not possible the catch proportions are determined by technology and the state of nature. Campbell and Nicholl use the data described in Section 3.2.3 above to test various hypotheses about the determination of the proportion of yellowfin in the catch of purse-seine vessels. They establish that the proportion of yellowfin is higher in free-school than in log sets ; that U.S. purse-seine vessels are better suited than Japanese vessels to make free-school sets ; and that, in fact, U.S. vessels are more likely to make free-school sets. They found no strong evidence that certain vessels within the U.S. fleet were consistently able to catch a higher proportion of yellowfin, or that this could be accomplished by choice of fishing ground.

Having established that the choice of the type of set influences the proportion of yellowfin harvested, Campbell and Nicholl then proceed to the main part of their analysis which is the estimation of supply curves derived from a generalized Leontief revenue function, assuming that in the short-run vessels act as revenue maximizers. The form of the revenue function is given by equation (2.1) and equation (2.2) describes the supply functions which are obtained through the assumption of revenue maximization. The supply functions are estimated on a per unit of effort basis.

If targeting is not possible, the input-compensated price elasticities of supply of both species, given by equations (4.1) will be zero. The only effect of product prices on harvests will be through their effect on the level of fishing effort. It can be seen from equations (4.1) that zero input-compensated price elasticities imply $\beta_{ij} = 0$, $i \neq j$. In other words,

$$\epsilon_{ii} = -\tfrac{1}{2} \sum_{j \neq i} \beta_{ij} (P_j / P_i)^{1/2} (E / Q_i)$$
$$\epsilon_{ij} = \tfrac{1}{2} \sum_{j \neq i} \beta_{ij} (P_j / P_i)^{1/2} (E / Q_i) \qquad (4.1)$$

the hypothesis of targeting can be tested by estimating the supply curves (2.2) and ascertaining whether the coefficient on relative price in the supply per unit effort function is significantly less than zero.

Campbell and Nichol test the hypothesis of targeting for both the Japanese and U.S. purse-seine fleets operating in Papua New Guinea's EEZ in the period 1983-87. They find no evidence of targeting by the Japanese fleet, but fairly strong, though not conclusive, evidence of targeting by the U.S. fleet. This result is consistent with the finding that U.S. vessels are better suited to making free-school sets which tend to yield a higher proportion of yellowfin.

Because of the inconclusive nature of their results, Campbell and Nicholl report alternative estimates of the various elasticities which are needed to estimate the cost of reducing purse-seine yellowfin catches by means of an ad valorem royalty. These elasticities are :

$$\varepsilon_y = \varepsilon_{yy} + \varepsilon_{yE}\, \varepsilon_{EPy}$$
$$\varepsilon_s = \varepsilon_{sy} + \varepsilon_{sE} \cdot \varepsilon_{EPy} \qquad (4.4)$$

where $\epsilon_y$ and $\epsilon_s$ are the percentage effects on yellowfin and skipjack harvests of a 1 % change in yellowfin price,
$\epsilon_{yy}$ and $\epsilon_{ys}$ are the input-compensated price elasticities,

$\epsilon_{yE}$ and $\epsilon_{sE}$ are the product specific scale elasticities,
and $\epsilon_{EPy}$ is the elasticity of demand for effort in response to a change in yellowfin price. The estimate of $\epsilon_{EPy}$ is based on the assumption that vessels are in long-run equilibrium with respect to the level of effort they devote to the fishery. This assumption was tested and found to be supported by the data. The estimates of these elasticities evaluated at mean values of the variables are reported in Table 1. The estimates tell two very different stories about the flexibility of the purse-seine fleet. In the targeting case $\epsilon_y = 5.249$ and $\epsilon_s = -5.247$ ; whereas in the no targeting case $\epsilon_y = 0.00012$ and $\epsilon_s = 0.00016$.

In the targeting case a policy of discouraging the harvesting of yellowfin through the imposition of a royalty is considered. The elasticity estimates indicate that a 1.9 % ad valorem royalty on yellowfin would reduce the yellowfin harvest of the average purse-seine vessel by 10 % and increase its skipjack catch by roughly the same proportion. Since skipjack is regarded as an under-exploited species there is no need for concern about the impact of the increased purse-seine skipjack catch on the pole-and-line fishery which mostly catches skipjack. The royalty causes a small reduction in fishing effort and the net of royalty revenue of the average vessel fishing in Papua New Guinea's EEZ falls by 2.4 %. The real economic cost of the royalty is given by the fall in revenue less the share going to the host country, and less any increase in revenue from transfering effort to another fishery. Campbell and Nicholl's estimate is that the cost of the policy is negligible.

If targeting is not possible, the relative price of yellowfin is not an effective policy variable. A policy of reducing juvenile yellowfin harvests would need to operate by discouraging purse-seine effort. This could be done by increasing the per unit effort access fee payable. Given, as noted above, that individual vessels in the sample are contributing their long-run equilibrium levels of effort to the fishery, an estimate of the elasticity of demand for effort with respect to the cost of effort can be calculated. The estimate is $\epsilon_{Ec} = -0.89$ (t-ratio - 2.467). Using this information together with the elasticity estimates reported in Table 1, it can be calculated that a 10 % decline in yellowfin harvest by the average vessel would result from a 21 % increase in the cost of effort through an increased access charge levied on a per unit effort basis. The cost to the average vessel in terms of reduced gross revenue is estimated to be 12 %. The 12 % fall in vessel revenues would likely be partially offset by increased revenues from fishing elsewhere. The decline in effort contributed by the average vessel to the EEZ can be calculated from the elasticity $\epsilon_{Ec}$ to be 19 %. The economic cost of the policy is the deadweight loss resulting from the increase in the access charge. As a percentage of monthly vessel revenue this loss is measured by one half of the percentage increase in the charge times the percentage reduction in effort. This can be calculated to be 2 % of revenue. The average monthly revenue for the sample of vessels operating in PNG's EEZ is $US333,000, so that the average monthly per vessel cost of the policy is around $6,600. Since the additional access fee payments are a transfer, being a benefit to the host country and a cost to the vessels, they are not relevant to the calculation of economic cost.

It is obvious from the above calculations that the cost of a policy of limiting catches of juvenile yellowfin depends upon the technology of the two-species production function. If there is non-jointness in inputs, targeting of individual species is not possible. This means that a decline in yellowfin catch will be accompanied by a decline in skipjack harvest. Alternatively, if the production function exhibits jointness in inputs, vessels can substitute skipjack for yellowfin in their harvests. The cost of the policy is then reduced to approximately the difference between the value of the foregone yellowfin and the increased skipjack catch. Campbell and Nicholl's results indicate that the cost of reducing per vessel yellowfin harvests by 10 % is negligible if targeting is possible, and around 2 % of revenue if it is not.

## 5. CONCLUSIONS

It is clear from the example discussed in Section 4 of the paper that the issue of targeting is of considerable practical importance in the economic analysis of the optimal allocation of the yellowfin stock between two fisheries. There are many other examples of fishery management issues where information about the multi-species production technology is required. An obvious example is the design of an ITQ management system for a multi-species fishery. The technique of analysis described in this paper can be readily applied to provide the information required.

# Portfolio Selection in Fishing Strategies in a Multispecies Trawl Fishery [1*]

**Susan Hanna**

Department of Agricultural and Resource Economics, Oregon State University, Corvallis, Oregon 97331 USA

ABSTRACT

*This paper examines the selection of fishing strategies in the West Coast U.S. groundfish fleet. The analysis in this paper is the beginning step in the definition of portfolio characteristics of fishing strategies and to examine the implication of portfolio selection in fishing strategies for fishery management. Fisheries are commonly defined and managed on a biological, single species basis. Linkages between stocks created by the operation of multipurpose fishing fleets create new fishery systems that cross species boundaries. Linkages between fisheries have both a biological and economic basis. This paper describes an important three-fishery system on the West Coast : groundfish trawl, shrimp trawl, and crab pots. The nature of fishery interactions is described. Factors linking the fisheries are detailed, including biological dynamics, economic dynamics, and risk reduction strategies. Implications of the three-fishery system for fishery management are discussed in the context of the timing of fishing seasons, interstate fishing effort, access limitation, and multifishery management.*

## 1. INTRODUCTION

Fisheries are commonly defined and managed by the biological distinctions of fish populations. Biologically-based definitions of fisheries are an outgrowth of years of fisheries management in which quotas have been set according to best estimates of the reproductive requirements of a single stock. On the few occasions that groupings of stocks do occur in management, they are at most groupings of similar categories of species ; e.g. finfish, shellfish.

1. Paper to appear in *Journal of Shellfish Research* 1992. An earlier version of this paper was presented at the Conference of the National Shellfisheries Association, Portland, Maine, June 23-27, 1991.

* This publication is the result of research sponsored by Oregon Sea Grant with funds from the National Oceanic and Atmospheric Administration, office of Sea Grant, Department of Commerce, under Grant No. NA85AA-D-SG095 (project no. R/ES-13) and from appropriations made by the Oregon State Legislature. The U.S. Government is authorized to produce and distribute reprints for governmental purposes, notwithstanding any copyright notation that may appear hereon. Joint research with Courtland L. Smith on fishing patterns in the West Coast trawl fleet provided background to the discussion. Review comments of Eric Thunberg and Paul Heikkila were extremely helpful. The assistance of Jim Golden, Jerry Lukas and Jean McCrae of the Oregon Department of Fish and Wildlife in providing research reports and unpublished data is gratefully acknowledged.

Although undertaken for legitimate conservation reasons, biologically based definitions of fisheries miss an important element of fishery structure and function : system properties which result from the linkages between stocks created by the operation of multipurpose fishing fleets. Such linkages cross species and species category lines, and may include, for example, both shellfish and finfish species caught by multipurpose vessels using an array of gears.

The history of development in capture fisheries has been one of increasing degree of interactions between target fisheries. In the initial stages of fishery development, stock abundance may allow fishermen to target single stocks or assemblages of similar species. As the fishery develops, the increase in fishing effort and the concomitant decrease in population levels results in the need for fishermen to diversify their fishing strategies. In the West Coast groundfish fishery, for example, over time fishermen have diversified over the number of groundfish species as well as over the number of fishing activities in groundfish and other fisheries. (Carter 1981 ; Hanna 1991).

Once multispecies or multifishery fishing strategies are established, single-species biologically-based management approaches become obsolete, reflective of an earlier and simpler stage of interaction between human systems and fish populations. Multifishery fishing strategies define a new fishery environment which requires that management broaden its approach from biological considerations alone to a system of biological and economic components.

One implication of multispecies and multifishery fishing strategies is that components of fishing effort become more heterogeneous and therefore more difficult to link to a single population of fish. Wilen (1979) notes that because fishing technology is flexible, attempts to manage fisheries on the basis of restrictions placed on only a few components of effort are futile. Lieberman (1986) supplements Wilen's argument about flexible technology by arguing for an approach to fishery management that includes social as well as technical factors and is explicitly dynamic to accommodate for changing fishing patterns. Golden (1991) details the structure of "transfer capacity" in the West Coast trawl fleet which introduces complexity into the definition of a fleet.

Charles (1989) concludes that because one component of management is to predict the response of both fishermen and fish stocks to changing fishery conditions, management must account for the joint dynamics of both fish stocks and fishermen. Similarly, in earlier work I describe the increasing diversification of assemblage fishing in the West Coast groundfish trawl fishery and argue for using the economic and biological properties of groundfish assemblages as the structural basis for management (Hanna 1987). Mitchell (1982) notes that understanding the tradeoffs facing fishermen in their choice of fisheries is necessary for adequate control of multispecies fishing effort.

A common multifishery interaction on the West Coast exists in the Dungeness crab (*Cancermagister* ), pink shrimp (*Pandalusjordani*), and groundfish (*Sebastes* spp., flatfish, and roundfish) fisheries. The dynamic relationship between these finfish and shellfish fisheries provides a classic example of fishery linkages which create a new definition of a fishery system.

This paper begins by describing the historical development and current status of groundfish, shrimp and crab interactions. Data from Oregon fisheries are used to illustrate the interaction. Next, the nature of these linkages are outlined through the identification and analysis of several factors which create the biological and economic dynamics of these fisheries. In the following sections, several management questions related to these multifishery interactions are discussed, including implications for system management in this fishery and others.

## 2. MATERIALS AND METHODS

Data on Oregon fisheries were acquired from several sources. Summaries of landings and gross revenue by fishery are published by the Oregon Department of Agriculture (1990). Unpublished data on individual vessel landings by gear type were provided by the Oregon Department of Fish and Wildlife. Data on individual vessels cover landings in Oregon from 1977 - 1990 by the three major gear types in the groundfish, shrimp and crab fisheries : trawl and pots. Yearly summaries of Oregon crab and shrimp fisheries appear in a series of reports (Demory 1991 ; Bruneau 1980 ; Jones and Hannah 1991 ; Lukas 1978 ; Oregon Department of Fish and Wildlife 1984 ; Saelens et al 1981 ; 1982 ; Saelens 1983 ; Saelens and Zirges 1985 ; Zirges and Robinson 1980). Histories of fishery development and regulation are presented in documents of the Pacific Fishery Management Council (1979 ; 1981 ; 1990).

Two major categories of fishery participation strategy are defined : specialists and generalists. The categorization of fishing strategy as specialist or generalist, advanced by Smith and McKelvey (1986), depends on the number of fishing

activities in which a fisherman participates. Specialists pursue a single fishing activity and adapt to a changing environment by modifying this activity. Generalists adapt to change by adopting an array of fishing activities. Specialists are defined here as fishermen who in a given year pursue only one fishery within the three fishery system. Generalists are defined as fishermen who in a given year use a fishing strategy which includes more than one of the three fisheries.

Because this paper looks at data from the trawl and pot fisheries only, the strategy categories are defined within the context of these two gear types. The terms "specialist" and "generalist" are used in the context of this trawl-pot fishery system definition. Therefore crab fishermen who are defined as "specialists" are specialists within the context of the three target fisheries discussed herein. These same crab fishermen may in fact develop generalist fishing strategies which combine crab fishing with line fisheries such as albacore and salmon. For the purposes of simplicity of discussion, the paper is limited in focus to the three-fishery system of groundfish trawl, shrimp trawl and crab pot gear. However, the conclusions reached about management of this system also apply to other strategy combinations.

## 3. WEST COAST SHELLFISH-FINFISH FISHERY INTERACTIONS

One component of fishery interaction is the timing of fishing seasons. Existing Oregon fishing seasons for crab, shrimp, and groundfish are depicted in Figure 1 (Oregon Department of Fish and Wildlife 1991). The Dungeness crab ocean season (pot gear) opens in December and continues until August. The groundfish trawl fishing season begins in January and continues until quotas are filled in the fall, with specific closing dates varying by species. Season length is regulated to some extent by trip quotas which are set to prevent a glut of landings at the beginning of the fishing year. The shrimp fishing season opens in April and generally continues until October.

Figure 1 illustrates that for 10 months of the year, from January until October, fishing seasons of the three fisheries overlap. The existence of overlapping seasons means that fishermen with vessels capable of fishing any of the three fisheries can choose between fisheries. Fishermen will choose a fishery or combination of fisheries on the basis of expectations about earnings, expectations about stock abundance and prices, and costs of investing in or changing gear.

The proportion of the fleet using a specialist strategy varies from fishery to fishery. The proportion of specialists also varies within a fishery over time. Table 1 illustrates the range of proportion of each fleet which participated in a specialist strategy in the years between 1977 - 1990. Percentages represent the proportion of boats landing that species category in a given year which land only that category.

Within the three-fleet combination of groundfish trawl, shrimp trawl and crab, fishermen using crab pot gear tend to use more specialized strategies than either shrimp or groundfish trawlers : an average of 81.8 % of the crab fleet fished only for crab during the time period, with small variation about the mean. This high proportion of specialists is due in large part to a masking effect of the database. The crab fleet includes both trawl-pot boats which use trawl gear for shrimp and groundfish and pot-troll boats which use pot and line gear to pursue crab, salmon and albacore (Fletcher et al. 1988 ; Demory 1991). The pot-troll boats do not have the capability of using trawl gear to catch shrimp or groundfish. Of the boats which are estimated to be trawl capable, the percentage of crab specialists is much lower. For most commercial fishermen, the crab season is not long enough to sustain a specialist crab fishing strategy.

The proportion of specialist shrimp trawlers which landed only shrimp in a given year varied between 51 and 71 % in the 13 year period, averaging 60.4 %. The proportion of specialist groundfish trawlers landing only groundfish in a given year was the smallest (49.2 %) of the three fisheries and had the largest variation about the mean. Some of the specialist vessels change their specialization from year to year ; for example, a fisherman may fish only shrimp one year, only groundfish the next.

The most common combination of fishing strategies in the specified three fleet combination is the groundfish/shrimp combination (Table 1). The number of boats using this strategy is calculated as the number of boats whose landings are primarily groundfish, who also land shrimp. The pursuit of this fishing strategy varies widely, from 11 to 71 % of the total number of groundfish boats over the time period. The shrimp and crab combination strategy comprises between 15-36 % of the vessels landing shrimp. This combination is economically important to some fishermen who fill in the period of closed shrimp season with two or three months of crab fishing (Zirges and Robinson 1980). The current fishing season structure, based on times of biological availability, promotes groundfish-shrimp and shrimp-crab as the most compatible strategy combinations (Figure 1).

Port differences influence the choice of fishing strategy. Oregon has three major fishing ports : Astoria, Newport, and Coos Bay. Astoria has the largest number of groundfish specialists. Severe winter weather prevents many Astoria fishermen from actively pursuing crab fishing. Newport is the most diverse of the three ports, with all fishing strategies represented. The most common generalist strategy in Coos Bay is the groundfish and shrimp combination (Smith and Hanna 1991).

## 4. MULTIFISHERY LINKAGE FACTORS

The fishing strategies which link the three fisheries are the result of incentives created by both biological and economic dynamics.

### *4.1 Biological Dynamics*

The changing patterns of landings of crab, shrimp and groundfish between 1970 and 1989 are a partial representation of the biological variation of stocks (Figure 2). Landings of Dungeness crab reflect well-recognized but little understood population cycles. High points in landings occurred in 1970-71, 1977, 1980. Intra-year fluctuations are caused by variation in the timing of the molt period which influences both the catchability and the "fullness" of crab (Demory 1991).

Shrimp populations are also subject to cycles. Peaks in Oregon landings in 1977, 1978, and 1989 reflect recent cycle crests. Variation in the timing of spawning will also affect fishing, as seasons are set to protect gravid shrimp. Deterioration in flesh quality during spawning also influences the timing of fishing for shrimp (Zirges and Robinson 1980).

Groundfish landings increased continually between 1977 and 1982 as post-Magnuson Act fishing effort fished down the surplus of relatively unexploited stocks. Substantial in-year variation in landings exists as a result of seasonal onshore-offshore migration of stocks (Hanna 1987). Flesh quality of some species, e.g. Dover sole, is affected by season and water depth (J. Easley 1990). Community dynamics of groundfish assemblages, i.e. the structural compensation to selective harvesting of species, are still little understood (Tyler et al 1982). Since 1982 various groundfish regulations have been put in place to maintain stocks at equilibrium yield levels, including single-species trip quotas and some initial attempts at assemblage trip quotas (Pacific Fishery Management Council 1990).

Population cycles, inter-year variability in stock location, and intra-year changes in location, spawning periods, and molt periods create a system of biological relationships characterized by high levels of variability. West Coast fishermen respond to this variability in their formation of expectations about biological influences on fishing opportunities in groundfish, shrimp and crab. Fishermen's expectations in turn underlie their planning and investment decisions which drive the distribution of fishing effort linking the three fisheries.

### *4.2 Economic Dynamics*

Economic dynamics are also at work creating connections between the three fisheries. Some of these dynamics reflect the results of individual fishermen's decisions, others reflect economic forces at levels beyond the control of individual fishermen.

The influence of various economic factors in directing fishing effort between the three fisheries underlies patterns illustrated in Figure 3, which shows vessels landing in Oregon ports between 1977 and 1989. It is important to note that because vessels participate in more than one of these fisheries, a single vessel may be represented in the shrimp fishery in one year, and the crab fishery in another year. Fishermen using specialist strategies will be represented in only one fishery in a given year, although they may be represented in different fisheries in different years. Fishermen using generalist strategies will be represented in more than one series in a given year.

A major driver of the economic dynamics of the fishery are individual fishing strategies developed to reduce the risk posed by a variable earnings environment. Changes in both landed quantity and exvessel price in the three fisheries lead

to large variability in exvessel gross revenues to fishermen, illustrated in Figure 4. In any economic system, economic variability and the uncertainty it creates lead risk-averse people to adopt various uncertainty-reducing strategies. One of the common strategies used to reduce economic variability is to diversify over several sources of revenue. Multifishery fishing strategies are an example of such diversification.

Diversification usually, but not always, benefits fishermen in the form of reduced variability of landings and earnings. Table 2 illustrates one of these benefits : reduced year-to-year variability in production and earnings. Variability is measured as the coefficients of variation (c.v.) of landings and gross revenues (revenues before costs) for the various fishing strategies.

Looking first at quantities landed, three specialist strategies of groundfish, shrimp, and crab show coefficients of variation in quantities landed of 49 %, 53 %, and 54 % respectively. Groundfish fishermen who also fished shrimp (strategy G/S) were able to reduce the c.v. of their landings to 38 %. By adding a third fishery to their fishing strategy, they realized a further reduction of the c.v. of their landings to 35 %. Groundfish fishermen were able to stabilize inter-year production by increasing the number of fishing activities.

The reduction in variability of landings for shrimp fishermen through generalization of strategy showed a similar trend. Specialist shrimp fishermen had a c.v. of landings of 53 %. Adding crab fishing to their strategy reduced the c.v. of landings to 48 %. Fishermen who fished the groundfish/shrimp combinations had even lower c.v.'s ; 38 %. A generalist strategy which included all three fisheries lowered the c.v. to 35 %.

For crab fishermen, adopting a generalist strategy reduced the variation of landings from 54 % to 48 % when shrimp fishing was added, to 35 % when the fishing strategy included all three fisheries.

In terms of stabilized earnings, where earnings are represented here by average gross revenues, the benefits to fishermen of adopting generalized fishing strategies are mixed. In the case of shrimp fishermen, the addition of groundfish fishing to their strategy reduces variability in average gross revenues from 50 % to 37 %. Variability in earnings is reduced still further to 34 % with the addition of the third fishery, crab, to the strategy.

For groundfish fishermen, the coefficient of variation of a combined groundfish/shrimp strategy (37 %) is actually greater than for groundfish alone (35 %), but is reduced slightly to 34 % with the addition of the third fishing activity, crab, to the strategy. The addition of crab to the groundfish strategy also increases the c.v. of average gross revenues. This phenomenon is largely due to the lower variability of landings of groundfish and fairly constant exvessel prices for groundfish species over the time period examined. However, the continued existence of groundfish/shrimp generalists indicates that other factors besides stability in earnings are important to fishermen in this fishery. Despite the failure to reduce variability in earnings through this strategy of groundfish and shrimp, trawl fishermen reap benefits from the combination in the form of higher, albeit cyclical, earnings.

In contrast to the other two types of specialists, crab fishermen gain nothing in reduction of variability of revenues through the adoption of generalist fishing strategies. Variability in earnings from crab fishing alone was 26 % over the time period, for crab combined with shrimp it was 37 %, and for crab combined with shrimp and groundfish it was 34 %. This phenomenon is due in part to the influence of the large number of very small specialized crab vessels in the "fleet" database which land small, unvarying quantities of groundfish throughout the season and from year to year.

A second major element of individual decision making which drives the economic dynamics of the groundfish-shrimp-crab fishery are the short-term effort responsiveness to changes in relative prices of groundfish, shrimp, and crab, changes in regulations, market conditions, and processor arrangements. Fishing effort is the outcome of a multicomponent choice set which includes expected net earnings of the primary fishery, expected net earnings of substitute fisheries. The choice set is modified by a constraint set which includes available technology, regulations, biological availability, processor limits, and general market conditions.

The short term responses between fisheries are extremely complex, as evidenced by the groundfish-shrimp interaction between 1979-1989. Figure 4 illustrates the changes. Between 1979 and 1983, real shrimp prices were generally increasing, while real groundfish prices were in general decline. However, volumes of available groundfish were high, and the increase in shrimp prices did not attract increases in the number of groundfish fishermen who landed shrimp. Processor constraints also played a role, as groundfish processors were reluctant to diversify their operations to include shrimp. In 1984, shrimp landings were low despite high prices, as the stock responded to the 1983 El Nino southern oscillation event (ENSO) (Jones and Hannah 1991). Between 1985-1987, average real shrimp prices increased 89 %,

from $.35 to.66. This price increase was followed by a corresponding increase in the proportion of groundfish vessels who fished the groundfish/shrimp combination activity : from 31 % in 1985 to 58 % in 1987. During this same period, groundfish prices were low as processors imported cheaper Canadian product. The proportion of groundfish specialists fell from 69 % to 42 %. Between 1987 and 1989, real shrimp prices fell 42 % to an average of $.33, but the percent of groundfish vessels fishing the groundfish-shrimp activity remained at 58 %. The price responsiveness of substitution between groundfish and shrimp was diminished over this period due to regulatory constraints in groundfish which introduced strict quantity controls on landings per trip.

Fishing in a single activity is often interrupted when price disputes between fishermen and processors cannot be resolved. For example, a mid-season downward price adjustment the 1989 Oregon shrimp fishery interrupted shrimp landings for a period of one month as processors and fishermen negotiated prices. Large landings early in the season left processors with large inventory holdings, leading processors to lower prices offered as a means to reduce inventory and cover storage costs (Jones and Hannah 1991).

Markets and general economic forces outside the control of individual fishermen are the second driver of economic dynamics. The exvessel market for groundfish, shrimp and crab is influenced by an array of economic factors. One is the buying patterns of fish processors. Oregon processors have at times objected to simultaneous landings of crab and shrimp, preferring to direct labor and equipment to one species (Zirges and Robinson 1980). In the period of early expansion of the groundfish fishery, many groundfish processors would buy only groundfish from groundfish trawl vessels, forcing a degree of specialization on vessels. In recent years, limitations on the supply of groundfish and shrimp have meant that processors have been more willing to buy both groundfish and shrimp from individual vessels (R. Young 1991).

Fluctuations in the exchange rate also influence the exvessel market for Oregon-caught groundfish, shrimp and crab. When foreign source groundfish are available at lower price than Oregon groundfish, West Coast processors have substituted imported groundfish for local groundfish in their production line. For example, in 1985 and 1986 a strong U.S. dollar in the Canada-U.S. exchange rate created a situation favorable to the import of relatively cheaper Canadian groundfish by U.S. processors. As Canadian groundfish were substituted for U.S. groundfish at the processing level, many vessels redirected their effort from groundfish to shrimp (Figure 3).

Finally, in each of the three fisheries ex-vessel prices paid to fishermen are influenced by larger national or international markets characterized by their own substitution relationships. For example, Oregon wild shrimp compete in regional, national and international markets with cultured shrimp. Dungeness crab compete domestically with surimi-based crab analogues and in a European export market with other crab species and substitute shellfish species (Demory 1991). Groundfish compete at the retail level with other protein sources, namely poultry (P. Leipzig 1990).

## 5. IMPLICATIONS OF MULTIFISHERY LINKAGES FOR SYSTEM MANAGEMENT

Both generalist fishing strategies and inter-year changes in specialist strategies create linkages between the fisheries which in turn create unique management issues not faced in specialized fisheries. Major issues in the management of the West Coast groundfish, shrimp and crab fisheries include the timing of fishing seasons, the management of interstate fishing effort, the limitation of access to fishing opportunities, and the economic attributes of multifishery activities.

### *5.1 Timing of Fishing Seasons*

The existence of an array of choices for fishermen who fish generalist strategies means that the composition of a fishing fleet is not static, but varies within and between seasons as fishermen combine fishing activities into strategies of their choice. Predictions of actual fishing effort on an individual stock are therefore difficult to make, but are assisted by an understanding of economic linkages and of the proportion of the fleet with transfer capacity.. The timing of fishing seasons becomes a critical factor in the management of effort levels and in the time spacing of effort in a single fishery. Setting seasons on a per-fishery basis in isolation of other fisheries in the system guarantees that one fishery's season will generate external impacts on another fishery.

There are two general complementary outcomes of coordinated timing of fishing seasons across fisheries. The first is to maximize the probability of controlling the timing and level of fishing effort on various stocks. The second is to maximize

the planning and coordination of the fishing year in ways that allow explicit consideration of enhancing the landed value of fish. Fishery interactions require that for maximum management effect in these two areas, the timing of fishing seasons should be decided on a coordinated basis with both biological and economic linkages taken into account. Pre-season information on market conditions (demand, availability of substitutes, expected exvessel price) combined with information on biological conditions (stock size, recruitment, flesh quality, timing of molt) can be used to good effect in the planning of season timing.

For example, as Figure 1 illustrates, managers have the ability to lessen the impact of fishing effort on Dungeness crab in the early season by delaying the season opening one month to coincide with the groundfish season opening. By the same token, managers may pace crab landings throughout the season by avoiding the initial surge of fishing effort on December. The potential economic benefits of paced landings include the avoidance of landings gluts which depress market prices, and the harvest of "full" animals. The coincidence of the shrimp and groundfish seasons combined with the popularity of the shrimp-groundfish strategy combination provides the opportunity to alternate open and closed periods in these two fisheries if needed to lessen effort impacts on stocks or avoid market gluts. Joint groundfish-shrimp seasons could be planned on the basis of a market strategy to maximize joint value.

### *5.2 Interstate Fishing Effort*

The crab, shrimp, and groundfish fisheries on the West Coast are managed under different jurisdictions in a mixed system of regulations. Although Dungeness crab is regulated separately by California, Oregon and Washington, no state's system of regulations operates in isolation. The timing and quantity of crab landings in a given state are influenced by the timing of seasons in a neighboring state. For example, in the years when Washington crabs molt late and are not available to the fishery at the December 1 opening, the Washington fleet shifts south for December fishing. The effect of effort location shifts is to increase the early-season fishing pressure on Oregon stocks as well as create landings gluts in Oregon ports and markets (Demory 1991 ; Heikkila 1991).

In the fall of 1990, a Tri-State Dungeness Crab Committee of crab fishermen was organized under the auspices of the Pacific States Marine Fisheries Commission to address the interstate effort issue and other concerns facing the crab fleet. In the organization of the committee, attempts were made to ensure representation from each port and vessel size class. Five issues were defined by the industry group for discussion and negotiation : early season opening date to be responsive to molt condition, late season closing date to respond to molt condition, a moratorium on new entry, enforcement of preseason gear placement regulations, and uniform gear marking (P. Heikkila 1991).

Shrimp have been managed under a license limitation system in Oregon since 1979 (Zirges and Robinson 1980 ; Saelens and Zirges 1985 ; Jones and Hannah 1991). No limitation on shrimp licenses exists in Washington or California. The Oregon license limitation program varies the number of permits available for purchase according to estimated of biological availability and includes a provision for commercial fisherman licensed to fish shrimp in other states to purchase up to six "single delivery" licenses per year for landing shrimp in Oregon ports. Since 1989 the number of permits has been limited to 187, with new permits to be sold by lottery only when the number of permits falls below that number. The single delivery provision creates a situation easily taken advantage of by cross-border fishing. Each fisherman in the Washington shrimp fleet, can fish in federal waters off Oregon and land in Washington, or buy 6 single delivery licenses to use for bad weather landings in Oregon (Oregon Department of Fish and Wildlife 1991).

Groundfish, under coordinated state and federal management jurisdiction, is managed consistently in California, Oregon and Washington. Nevertheless, the existence of mobile, multipurpose fleets means that the location of effort concentrations are difficult to predict. Under the current system, managers must account for a confusing array of sources of effort on the groundfish stock in question in the design of regulations to reach conservation goals for each stock. Within the three-fishery system, the practice of partial-system regulation has the effect of redirecting effort from one state to another as well as from one stock to another.

### *5.3 Access Limitation*

The crab, shrimp, and groundfish fisheries have each reached a level of exploitation which will require strong effort controls. Unless managers and industry members are willing to continue down the path of increasingly strict effort controls in the form of short seasons or trip quotas, some form of access limitation is the obvious answer.

The current regulatory situation is a tangle of different controls, based on political boundaries. Shrimp is managed by one of the three states - Oregon - in a license limitation system of questionable effectiveness in controlling effort. No license limitation exists in California or Washington. Under the Oregon system, licenses are in fact limited in number, but the number of licenses outstanding and the provision for "single delivery" license purchase enables high levels of effort to be maintained. Supported by strong year classes, shrimp landings were at record high levels between 1988-1990. The concern has been expressed that the fishery is vulnerable to the continued strong recruitment of age 1 shrimp and that without it the stock will not support current effort levels (Jones and Hannah 1991).

A federal license limitation program has recently been developed for three major gears in the groundfish fishery in all three states : trawl, longline, and pots. This program, adopted by the Pacific Fishery Management Council in September 1991, will be implemented in 1993. Groundfish will continue to have an open access quota set aside for fishermen not qualifying under the license limitation program.

Although none of the three states has an access limitation program for crab, recent developments on coordinated interstate management by the Tri-State Dungeness Crab Committee look promising for effort control. A moratorium date which closes options for new entry has been adopted. A process will be initiated to consider the implementation of a limited access program. The Committee has agreed that the long-term goal of such a program is to reduce both the number of crab pots and the number of boats. An individual quota system for pots will be one of the alternatives for consideration (P. Heikkila 1991).

A striking characteristic of the development of the groundfish limited access plan and the establishment of the Tri-State Dungeness Crab Committee has been the coordination between industry and managers. Although the move toward cooperative industry-agency management planning is promising, the element of fishery system planning is missing. Under current separate planning efforts, these three interrelated fisheries will have at best a piecemeal system of access limitation. Vessels excluded by a particular access limitation program will likely redirect fishing effort to substitute fisheries which remain open access. Regulatory inconsistencies between the three fisheries pose a further challenge to managers. The uncertainty created by the sporadic adoption of limited access programs has resulted in strategic positioning of fishermen to qualify in several fisheries in the expectation of continued limitation of their operations. Individuals fishing in new fisheries to qualify increase aggregate fishing effort, exacerbating the already difficult management task of controlling levels of exploitation.

### *5.4 Multifishery Management*

As discussed above, there are various economic reasons why fishermen engage in multifishery activity. Stocks vary in availability as oceanographic conditions affect spawning, molt, and recruitment. Stock variability creates variability in earnings from the fishery which in turn creates the incentive to diversify over several target species. Market conditions affect relative prices of substitute species. Generalist fishing strategies result from the biological and economic variability which are a normal part of any ocean system. The ramifications of continuing these linked fisheries on the traditional individual fishery basis are many : inconsistently timed fishing seasons, external market effects, and unpredictable effort shifts in response to piecemeal restrictions on access.

Multifishery system management could address these problems. An explicit recognition of the three fisheries as a fishery system for management would allow the design of a regulatory system that internalizes external effects of single fishery management. The traditional practice has been that fishery management proceeds along single species lines. Although recognition of multi-fishery interactions exists, the inertia of habit and traditional thinking have slowed the evolution of management to reflect actual fishery operations.

The practical question of how to implement management planning at the system level remains. This is not a trivial question and requires systematic development of a procedure within the context of the system at hand. However, some basic components of system management can be outlined here : system definition, supporting data, the planning process, definition of management goals, and system evaluation.

Defining the system to be managed is an element which is obviously dependent on context. In the case of the Oregon crab, shrimp, and groundfish system discussed in this paper, multi-fishery management would require a broader system definition. While crab, shrimp, and groundfish are the large-volume components of the system, a critical role is played for generalist strategies by the albacore and ocean salmon fisheries as well. System definition requires a thorough knowledge of fishery operations which cannot be acquired through secondary data sources.

Data to support analysis and monitoring of both biological and economic components of the fishery system, once defined, are of course a basic need. Current systems of data collection and entry are based on the historical practice of single-species management. The definition of a data base along single fishery lines presents a practical barrier facing analysts of fishing fleet activity. The activity of multi-purpose vessels is thus included in several data bases which are often formatted in uncoordinated ways, prohibiting cross-fishery analysis. A vessel may "drop out" of a data base once it switches fishing activity. Another difficulty with the current system of data storage is the tracking and analysis of multi-fishery fishing effort. Effort units are often multiple-counted as separate data bases are analyzed.

The planning process for fishery system management is also critical, and should include pre-season information on both the biological and economic components of the system as well as a clear definition of the authorized planning parties. The definition of the legitimate "players" comes from the context of the fishery itself. Coordinated planning, to be successful, will have to involve representation of all the commercial fishery constituents ; i.e. fishery managers, fishing industry, and consumers. Also necessary is a clear definition of objectives for the fishery system beyond the basic conservation goals.

Comanagement by managers and industry has taken various forms in the Oregon crab, shrimp and groundfish fisheries. Industry has played a strong and constructive role. Efforts to initiate discussions about limited access in the groundfish and crab fisheries originated in industry groups who felt that more effective management should be and could be implemented. Industry committees in both fisheries have been instrumental in outlining the problems to be addressed, defining management objectives, and discussing alternative means to reach goals.

One of the goals of multi-fishery management would be to avoid the problems illustrated by the case study of Oregon crab, shrimp and groundfish : uncoordinated timing of fishing seasons, interstate fishing effort shifts, and piecemeal regulatory programs. The coordination of multifishery seasons could minimize the surges in off-season effort in substitute fisheries. Interstate effort distributions could be stabilized through the coordination of state regulations and season timing. Bycatch issues, e.g. groundfish caught in shrimp trawls, could be explicitly addressed as components of a single system.

System evaluation will incorporate the other four elements : system definition, supporting data, the planning process, and the definition of management goals.

## 6. SUMMARY AND CONCLUSIONS

This case study of Oregon shellfish and finfish fisheries illustrate two principles which have application to other fisheries with multifishery activity. The first principle is that economic factors, although often not explicitly incorporated into management plans, are often instrumental in creating linkages between fisheries and so affect the efficacy of management plans. The second principle is that when linkages exist, management of fisheries must proceed on a level which recognizes these linkages and accounts for multifishery fishing strategies.

Fishery management on a system level which explicitly recognizes biological and economic linkages offers several potential benefits : coordinated timing of fishing seasons, more predictable control of the spatial and temporal components of fishing effort, and fewer unintended "external" impacts of regulations.

What we find instead in the management of these fisheries and indeed in the management of most capture fisheries is a jumble of biological controls mixed with political boundaries of jurisdictions, without an accounting of the economic forces creating interrelationships.

As populations of fishermen have increased and as fishing technology has become more sophisticated, fish populations have become more interconnected. The fishery is becoming smaller just as our political and economic world is becoming smaller. As the interconnectedness of fishery operations increases, it becomes increasingly important for fishery management to understand the heterogeneity of fishing strategies and their economic basis.

What is defined as a "fishery" has as much to do with human patterns of exploitation as with biological attributes of fish populations. The continuance of single-stock biological approaches to management is not sufficient to capture the full sphere of fishery components. It is also necessary to understand and account for the economic and social incentives facing people who catch and process the fish, and incorporate the human environment into a system of management. Defining new fishery systems is one approach.

RÉSUMÉ

*Les interactions entre les flottilles jouent un rôle majeur dans la dynamique des pêcheries. Ainsi, la gestion des pêcheries artisanales requiert une analyse des stratégies de pêche pour appréhender la diversité qui les caractérise. Dans cette communication, nous étudions plus particulièrement les stratégies de pêche à travers l'analyse statistique des journaux de bord (captures, temps de pêche, engins). A cette fin, nous avons utilisé les journaux de bord quotidiens (pour l'année 1989) des deux cents navires artisans de Boulogne-sur-mer, qui est le plus grand port du nord de la France. Dans un premier temps, les statistiques descriptives sur les calendriers d'activité, les espèces cibles et les caractéristiques des bateaux ont permis de mettre en évidence la concentration et la saisonnalité de l'activité des unités de pêche. Ensuite, une analyse factorielle sur la répartition mensuelle du chiffre d'affaires annuel permet d'établir une typologie de la flottille artisanale. Enfin, une analyse des stratégies des pêcheurs est réalisée à partir d'une classification automatique. Le principal résultat de cette typologie est que la diversité de la pêche artisanale en termes d'espèces, d'engins de pêche et de calendrier recouvre un ensemble de métiers bien spécifiés. L'identification des différentes stratégies montre les interactions entre les flottilles et les possibilités de réallocation de l'effort de pêche.*

ABSTRACT

*The interactions between fleets play a major role in the fishery dynamic. Thus, the management of small scale fisheries requires an analysis of fishing strategies to understand the diversity of the fisheries. In this paper, we focus on the fishermen behaviour through the statistical analysis of the log-book data (catches, fishing time, gears). For this purpose, we have used the daily log-books (for 1989) of the two hundred "artisanal" ships of Boulogne-sur-mer which is the main*

*port of northern France. At first, we compute some descriptive statistics upon the fishing calendar, the target species and the technical characteristics of the ships which give some informations about the concentration and the seasonality of the fishing activity. Then, we carry out a factorial analysis of the monthly shares of the annual gross-earnings to define a typology of the "artisanal" fleet. Finally, we perform a cluster analysis to identify the fishermen strategies. The main issue of this typology is that the diversity of the small scale fishery in terms of species, fishing gears and seasonality recovers a sum of well specified activities ("métier" in french) for separate groups of fishermen. The identification of the different strategies shows the interactions between the fleets and the possibilities of fishing effort reallocation.*

## 1. INTRODUCTION

La pêche artisanale est généralement caractérisée par un grand nombre d'espèces cible et de techniques de pêche. Ainsi, l'analyse des pêcheries pluri-spécifiques (multi-espèces, multi-engins) nécessite d'identifier les interactions entre les espèces et les flottilles.

Dans cette communication, nous nous intéressons plus particulièrement au comportement des pêcheurs à travers l'analyse statistique des journaux de bord (captures, calendrier d'activité, engins de pêche). Dans un premier temps, nous définissons une typologie de la flottille artisanale afin d'obtenir des groupes de bateaux ayant une activité homogène. Ensuite, nous interprétons le comportement de chacun des groupes grâce aux caractéristiques de leur activité.

La détermination d'un nombre limité de flottilles répond à la fois aux besoins de modélisation et de gestion des pêcheries. Elle nous amène à réaliser une classification à partir de nos résultats précédents. Ainsi, nous pouvons choisir un niveau d'agrégation qui nous donne un nombre réduit de flottilles qui soit cependant suffisant pour rendre compte de la diversité de la pêcherie.

Pour cette analyse, nous avons utilisé les journaux de bord quotidiens (pour l'année 1989) des deux cent cinquante bateaux artisans de Boulogne-sur-Mer qui est le plus grand port du nord de la France, et l'un des deux plus grands ports de France avec Lorient dans le sud de la Bretagne.

Dans la section 2, nous décrivons l'évolution de la flottille de pêche artisanale qui s'est fortement accrue durant les années quatre-vingt et qui représente 45 % de la valeur des apports en 1989. La troisième section est consacrée à une analyse statistique des journaux de bord pour définir une typologie des flottilles. Enfin, nous essayons d'identifier les stratégies de pêche en utilisant les résultats des analyses multivariées dans la section 4.

## 2. DYNAMIQUE DE LA PECHE ARTISANALE A BOULOGNE-SUR-MER

Boulogne-sur-Mer reste le premier port de pêche français pour quantités débarquées avec 65.000 tonnes (T) en 1989, mais n'est plus le premier port de pêche français pour la valeur des apports : le chiffre d'affaires de la pêche était de 570 millions de Francs (MF) à Lorient contre 510 MF à Boulogne pour cette même année.

L'évolution du secteur des pêches a été caractérisée, depuis le milieu des années soixante-dix (les captures les plus élevées furent de 145.000 T en 1973), par une diminution régulière des débarquements correspondant au déclin de la pêche industrielle [1]. Cette récession a été atténuée par l'expansion de la flottille artisanale jusqu'au milieu des années quatre-vingt, avant sa stabilisation.

Cependant, Boulogne-sur-mer est maintenant une place importante en terme de marché des produits de la mer (250.000 T en 1989) ceci étant en relation avec le développement des industries de transformation depuis le milieu de la dernière décennie.

Le développement de la pêche artisanale durant les années quatre-vingt a été favorisée par l'instauration de la ZEE Européenne en 1977 et par la forte valorisation des captures (ainsi, la sole représente 2 % des quantités débarquées à

1. L'appellation de "pêche industrielle" est donnée par rapport à la dénomination légale des entreprises industrielles en France. Les bateaux industriels de Boulogne sont des chalutiers de haute-mer de 55 mètres qui débarquent du poisson frais pour la consommation humaine.

Boulogne mais 15 % de la valeur de celles-ci). Deux principales composantes peuvent être distinguées dans cette flottille : il s'agit d'une part des plus petits navires (navires de *petite pêche*) qui ont une longueur de moins de 12 mètres et des marées de moins d'une journée et, d'autre part, des navires dits *"artisans "* [2]. Le tableau 1 résume la contribution de chacune des flottilles aux apports de Boulogne en 1989. On se reportera à Lemoine et al. (1988) pour une description détaillée des flottilles boulonnaises.

La flottille de petite pêche a été caractérisée par une forte croissance des trémailleurs et des fileyeurs au début des années quatre-vingt (Lantz et Célimene, 1989) : le nombre de navires s'est accru jusqu'en 1987 avant de stabiliser.

Par ailleurs, les bateaux les plus représentatifs de la flottille artisanale sont les chalutiers de 16-25 mètres (*"chalutiers étaplois"*). La puissance motrice de ces navires a augmenté de 20.200 KW en 1983 à 30.580 KW en 1990 (la puissance motrice par unité a progressé de manière encore plus rapide en passant de 325 KW à 495 KW durant la même période) : ceci explique que ces navires réalisent 43 % des débarquements en 1989. Toutefois, l'analyse des performances économiques de ces navires a mis en évidence la stagnation de leur rentabilité et de l'accroissement de leur endettement pendant ces dernières années.

## 3. TYPOLOGIE DE LA PECHE ARTISANALE

Les données utilisées pour notre analyse sont les statistiques mensuelles issues des journaux de bord qui sont collectés et informatisés par le CRTS (Centre Régional de Traitement Statistique qui est situé à Boulogne pour le Nord de la France). Les fichiers de données contiennent pour chaque marée de chaque bateau les informations suivantes [3] :

- Quantités et valeur de chaque espèce par catégorie commerciale (quand elles sont vendues en criée),
- Zone de pêche (par rectangle statistique pour les trois quart des captures, par rectangle CIEM autrement),
- Temps de pêche pour chaque engin.

Les données que nous venons de décrire représentent un fichier informatique de 3 mega-octets pour Boulogne-sur-mer en 1989. Ainsi, l'analyse des activités de pêche à travers une analyse statistique des fichiers de données implique l'utilisation des méthodes multivariées pour résumer l'information disponible.

Cependant, nous nous sommes intéressés au préalable aux corrélations entre les espèces, les engins et les zones de pêche. Cette étude a mis en évidence que les bateaux sont extrêmement spécialisés. Pour un mois donné, les combinaisons entre engins et espèces : par exemple, les chalutiers (chalut de fond) ne réalisent que 57 % des apports de cabillaud en janvier (compétition avec les filets) mais représentent 73 % des débarquements de cette même espèce en juillet. Ainsi, les statistiques univariées (corrélations, indices de concentration) nous ont permis d'observer que l'activité de chaque type d'unité de pêche est marquée par une forte saisonnalité. Nous avons donc décidé de faire porter notre analyse des correspondances multiples (ACM) sur les chiffres d'affaires (C.A.) mensuels.

Le choix d'un indicateur d'output plutôt qu'un indicateur d'input vient principalement de ce que la variable "C.A." peut être utilisée pour toutes les unités de pêche. A l'opposé, on ne peut pas utiliser un indicateur d'effort de pêche sans distinguer les navires suivant leurs caractéristiques techniques (engin, longueur, puissance). Un indice d'input ne peut donc qu'être que de nature différente suivant le type d'activité (qui lui-même peut varier suivant les saisons) : ainsi, le temps de pêche est pertinent pour un chalutier mais ne l'est pas pour un fileyeur.

La fiabilité des données utilisées a été pu être mesurée sur les chalutiers de plus de 20 mètres pour lesquels nous disposions d'un échantillon représentatif de comptabilités de navires. L'écart entre les chiffres d'affaires observés sur la criée et dans les données comptables est inférieur à 1 %. Toutefois, les unités de moins de 12 mètres n'étant pas tenues à l'époque (1989) de tenir un livre de bord, les débarquements des plus petites unités sont sans doute sous-évalués.

2. Cette flottille peut elle-même être subdivisée en deux catégories suivant que la longueur du navire est inférieure ou supérieure à 16 mètres et que la durée de la marée est de plus ou de moins de 3 jours.
3. Pour plus de détails on peut se reporter à Allard (1991).

Nous avons calculé la répartition mensuelle du C.A. annuel pour chaque unité de pêche pour éviter un effet de taille entre les différents types de navire. Puis nous avons construit un tableau disjonctif avec quatre modalités pour chaque variable mensuelle :

- 1 : Pas d'activité durant le mois,
- 2 : La part du C.A. est inférieur à 33 %, i.e. le bateau fait parti des 33 % des navires qui réalisent leur part du chiffre d'affaires la plus faible durant le mois considéré : faible activité durant le mois au regard de l'ensemble de la flottille artisanale,
- 3 : Part du C.A. compris entre 33 % et 66 % : activité médiane,
- 4 : Part du C.A. supérieur à 66 % : forte activité.

Le tableau disjonctif ainsi constitué comprend 48 modalités actives (12 mois * 4 modalités) et 255 individus (255 navires artisans). Nous avons ajouté les caractéristiques techniques (longueur, TJB, puissance motrice et année de lancement) et le C.A. annuel comme variables supplémentaires. Ces variables ont elles-même été réparties en quatre modalités.

Les quatre premiers axes expliquent respectivement 18.4 %, 8.6 %, 6.6 % et 4.8 % de l'inertie totale. La figure 1 représente la projection sur l'axe 1-2 (on se reportera à l'annexe 1 pour la signification des libellés).

Le premier axe oppose les modalités d'inactivité hors vacances estivales (janvier à juin : JV1 à JN1, septembre à décembre : SE1 à DE1) qui ont des valeurs positives aux modalités d'activité moyenne ou déjà importantes (indices 2 et 3 associés à l'ensemble des mois). Aux valeurs positives de l'axe correspondent les petites unités de faible longueur et TJB (L1,J1) et relativement anciennes (A1). A l'opposé, on trouve des unités de plus forte taille. De manière similaire, les C.A. totaux vont du plus fort au plus faible sur cet axe. Ainsi, la première distinction entre les unités de pêche artisanale se fait entre celles qui ont une activité régulière tout au long de l'année à celles qui ont une activité plus saisonnière et peuvent être éventuellement bloquées par les intempéries.

L'axe 2 oppose les activités saisonnières marquées de début d'année (janvier à avril : JV4 à AV4) à celles de fin d'année (septembre à décembre : SE4 à DE4) sans que nous puissions distinguer au regard des variables supplémentaires. Il devient alors nécessaire d'étudier les captures et les engins utilisés pour caractériser les navires. Nous reviendrons sur cette opposition entre deux groupes de navires dans la prochaine section (les unités de pêche correspondent respectivement aux groupes 3 et 2).

L'axe 3 permet de distinguer les fortes et les faibles activités durant la période mai-juin-juillet. Ceci correspond à une opposition entre grands et petits bateaux, ces derniers (et plus particulièrement les trémailleurs à sole) étant très actifs durant cette période. Enfin, l'axe 4 est déterminé par les unités de pêche qui concentrent leur activité sur la fin de l'année.

L'interprétation des axes permet ainsi de distinguer les bateaux qui présentent une activité très saisonnière (les plus petites unités) des grands navires artisans qui ont une activité plus régulière sur l'année. Ensuite, les unités se répartissent suivant la saisonalité de leurs activité. Il est intéressant de noter que les modalités définies à partir de la répartition mensuelle du chiffre d'affaires ne semblent pas se différencier sensiblement durant un même trimestre. Ceci va dans le même sens que l'approche trimestrielle retenue pour la modélisation bio-économique de la Mer du Nord par le CSTP (STCF North Sea WG, 1990).

## 4. CLASSIFICATION DE LA FLOTTILLE ARTISANALE

La classification a été réalisée à partir des coordonnées factorielles des 255 unités obtenues par l'ACM. Au niveau 8 (Groupes 1 à 8), nous avons calculé la moyenne, la médiane et les extremums des variables supplémentaires de l'analyse (puissance, année de lancement, C.A. annuel) qui ont permis d'observer une relative homogénéité au sein de chaque groupe (cf annexe 2).

De même, nous avons calculé pour chaque groupe et chaque mois les engins de pêche les plus utilisés, les espèces cibles et les zones de pêche fréquentées. Les cartes présentées en annexe 2 décrivent la concentration de l'activité des navires

(en terme de chiffre d'affaires) suivant les rectangles statistiques : alors que les groupes 1,2 et 3 travaillent presque exclusivement en Manche orientale, le groupes 6 et 7 ont une activité mieux répartie entre la Manche orientale et le sud de la Mer du Nord.

Le regroupement suivant fait apparaître quatre classes (groupes A à D) puis deux catégories (I et II). Le tableau 2 résume les caractéristiques des flottilles ainsi identifiées. Le regroupement au niveau 8 permet donc de distinguer les unités en terme de type d'unité (longueur, Tjb), d'engins de pêche, d'espèces cible, de zone de pêche et de saisonalité de l'activité. Au niveau 4, on différencie les navires en terme d'engins de pêche et de saisonalité. Enfin, au niveau 2 la flottille artisanale se répartie suivant que les bateaux se caractérisent par une activité régulière tout au long de l'année ou non.

Une analyse détaillée des flottilles les unes par rapport aux autres permet de mieux cerner les stratégies de pêche et les compétitions entre les différents types de pêche. A titre d'exemple, le groupe 2 est une flottille qui utilise des filets durant toutes les saisons sauf l'été où elle utilise le chalut. Cette flottille se caractérise par une très grande part du C.A. réalisé pendant les quatre derniers mois de l'année et capture principalement du cabillaud et de la sole. Les bateaux sont des unités de 14 mètres qui travaillent principalement en Manche orientale où ils réalisent 75 % de leur chiffre d'affaires. Toute mesure de régulation sur les filets se traduirait par une augmentation de la seconde activité de ces navires : le chalut. Dès lors ces unités pourraient rentrer en compétition avec celles du groupe 3 qui utilisent les mêmes engins de pêche et travaillent sur les mêmes zones.

## 5. CONCLUSION

L'analyse statistique de la pêche artisanale à Boulogne-sur-mer nous a montré que cette pêcherie qui est caractérisée par un grand nombre d'espèces capturées et de techniques de pêche utilisées recouvre un ensemble de "métiers" plus ou moins spécialisés. La diversité de la pêche artisanale doit donc se comprendre comme une multitude d'activités spécifiques plutôt qu'"une flottille" qui pêcherait beaucoup d'espèces avec de nombreuses techniques.

Chaque flottille pêche plusieurs espèces avec plusieurs engins tout au long de l'année mais réalise en général plus des deux tiers de son chiffre d'affaires avec au plus deux engins de pêche et moins de quatre espèces au cours du même mois. Ceci a pour conséquence, en terme de gestion des pêches, qu'il est difficile d'opérer des changements importants d'espèces cibles sans toucher très sensiblement au revenu des pêcheurs à court terme.

Enfin, les différences de stratégies de pêche met en évidence la difficulté d'une gestion globale de la pêcherie qui ne prendrait pas en compte les particularités et la dynamique de chaque flottille ainsi que les interactions entre celles-ci. Les outils de régulation "classiques" de l'effort de pêche (taille des maillages, quotas...) appliqués de manière uniforme ont un impact distinct suivant les bateaux artisans caractérisés par leur pluri-spécificité qu'il est donc important de préciser à travers l'identification de métiers.

TABLEAU 2.
CARACTERISTIQUES DES FLOTILLES ISSUES DE LA CLASSIFICATION

| Niveau d'agr. | Groupe | Nb de bateaux | Caractéristiques |
|---|---|---|---|
| 8 | 1 | 52 | petits chalutiers + autres engins, faible activité en 1989 |
| 8 | 2 | 18 | Filets, unités de 12-16 mètres |
| 8 | 3 | 20 | Chalut de fond + filets, unités de 12-26 mètres |
| 8 | 4 | 9 | Filets + chalut de fond, unités de 12-16 mètres |
| 8 | 5 | 30 | Chalutiers de 16 mètres, activité régulière |
| 8 | 6 | 29 | Chalutiers de 20 mètres, activité régulière |
| 8 | 7 | 57 | Chalut + filets, unités de 12-16 mètres |
| 8 | 8 | 40 | Chalut + filets, forte activité au printemps (unités de 12-16 mètres) |
| 4 | A=1+2 | 70 | Activité principale en fin d'année, unités de moins de 16 mètres |
| 4 | B=3+4 | 29 | Activité principale durant le premier semestre, |
| 4 | C=5+6 | 59 | Chalutiers étaplois |
| 4 | D=7+8 | 97 | Chalut + filets à activité régulière |
| 2 | I=A+B | 99 | Activité saisonnière marquée |
| 2 | II=C+D | | Activité régulière durant l'année |

## ANNEXE 1 : ANALYSE FACTORIELLE DES CORRESPONDANCES MULTIPLES

L'analyse factorielle des correspondances multiples a été réalisée à partir d'un tableau de 48 modalités (12 variables réparties en 4 classes) et 255 observations. Les modalités ont été construites à partir de la répartition mensuelle du chiffre d'affaires des 255 unités de pêche artisanale qui sont analysées. L'ACM a été réalisée sur le logiciel ADDAD.

Les libellés des variables ont les significations suivantes :

JVi, FEi, MSi, AVi, MIi, JNi, JTi, AOi, SEi, OCi, NVi,DEi : Janvier, Février, Mars, Avril, Mai, Juin, Juillet, Août, septembre, Octobre, Novembre, Décembre et i =1, 2, 3, et 4.

Li, Ji, Pi, Ti = Longueur, TJB, Puissance Motrice Power et Chiffre d'affaires et i =1,2,3 et 4.

Les indices i sont définis dans la section 3.

# The effect of government subsidies on the formation of collusions in an oligopolistic fishery

**Per Mickwitz[a] and Mikael Hildén[b]**

[a]Finnish Game and Fisheries Research Institute, P.O. Box 202, SF-00151 Helsinki, Finland

[b]National Board of Waters and the Environment, P.O. Box 250, SF-00151 Helsinki, Finland

ABSTRACT

*Subsidies are used widely in fisheries for many different objectives. A theoretical analysis using a Cournot model demonstrates that some systems of subsidization may create incentives to form stable collusions although a collusion would not be viable without subsidies. In a simulation using Finnish herring data this effect is obtained for reasonably realistic parameter values. The approach could form the basis for an extended analysis of the effects of the removal of subsidies, but an assessments would require more reliable data on demand and production functions of fishing enterprises and information on exit and entry behaviour of fishermen.*

## 1. INTRODUCTION

Producer subsidies are used by governments as policy instruments in many sectors throughout the world. In industrialized countries subsidies are often justified as means of correcting for market failures (e.g. Peacock 1990) whereas they are seen as initiators of development in foreign aid programs to developing countries (e.g. Greboval 1989). The liberation of trade has raised an interest in the macro economic effects of subsidies and OECD publishes regular reports on subsidization in the fisheries sector. In the US countervailing duties have been used against Canadian fish on the grounds of subsidies (Shrank et al. 1987, Rugman and Anderson 1987).

Subsidies have a large range of micro economic effects and the subject has been touched upon in several studies of fisheries economics. The efficiency of subsidies as policy instrument has been doubted by e.g. Copes (1978) and Jentoft

and Mikalsen (1987). Plourde and Smith (1989) and Hämäläinen et. al (1990) included subsides as a factor influencing share fishing. Kaitala and Leitmann (1991) and Kaitala et al. (1992) investigated the use of subsidies as an instrument for stabilization in fisheries.

In an earlier paper we presented the structure of the system of price subsidies in Finland (Hildén and Mickwitz 1990). In this paper we extend the analysis by a theoretical investigation of the potential role of subsidies in facilitating collusions formed by producers. Our study is based on a game-theoretic approach using a static game describing an oligopolist market with Cournot conjectures (e.g. Kreps 1990). In this simple model mergers have been examined and found to be nonviable, unless the merger succeeds in effectively monopolizing the market (Salant et al. 1983).

In order to capture some essential features of the Finnish fisheries the basic model has extended been to allow the inclusion of a heterogenous fleet consisting of two types of fishing enterprises and two production seasons. The second type has different marginal costs, but only the first type of enterprises is able to produce during both seasons. The fish population dynamics has been excluded because the present exploitation of the Finnish herring is at such a low level that the sustainability is guaranteed for a wide range of exploitation levels and exploitation strategies and chiefly limited by market conditions (Hildén 1991).

Using the model we examine two aspects of the price subsidization. First we analyze the general contribution of the subsidization to the total revenues under non-cooperation and cooperation. Thereafter we turn to the stability of the collusion formed by the enterprises belonging to the second group by examining the total revenues of an outsider and the insiders.

## 2. THE MODELS

### *2.1 Individual choice*

The basic model has two periods, the first we will call summer (s) and the second winter (w). Two different types of fishermen are identified. The fishermen within a type are assumed to be identical with n enterprises of the first type and m of the second type. The two types use different techniques with different costs. The techniques also differ in that the second type is able to fish only during summer.

The demand for fish by the processing industry in the summer is :

$$P_s = A - a^* \sum_{i=1}^{n} q_{is} - a^* \sum_{j=1}^{m} q_{js} \tag{2.1}$$

and in the winter it is :

$$P_w = B - b^* \sum_{i=1}^{n} q_{iw} - f^* \left( \sum_{i=1}^{n} q_{is} + \sum_{j=1}^{m} q_{js} \right) \tag{2.2}$$

$P_s$ = The price in the summer
$P_w$ = The price in the winter
$q_{is}$ = The quantity produced in the summer by a fisherman of the first type
$q_{js}$ = The quantity produced in the summer by a fisherman of the second type
$q_{iw}$ = The quantity produced in the winter by a fisherman of the first type
n = number of fishermen in the first type
m = number of fishermen in the second type
A,B,a,b,f = coefficients

We assume that A,B,a,b and f all are greater or equal to zero and that f<a and f<b, i.e. the quantities in the summer affects the price in the summer more than they affect the price in the winter and they also affect the winter price less than the quantity caught in the winter.[1]

The fishermen make their decisions on how much they should fish by maximizing their profit. The fishermen of the first type which can fish also during the winter, discount the profit from the second period. The decisions by the fishermen are made simultaneously.

The fishermen of the first type make the decision on production in the summer and in the winter by maximizing their total profit for $P > 0$ and $q > 0$ :

$$TR_i = (P_s - c_{is})^* q_{is} + \delta^*(P_w - c_{iw})^* q_{iw} - FC_i \qquad (2.3)$$

$TR_i$ = The revenue of a fisherman of the first type
$c_{is}$ = The marginal costs in the summer for a fisherman of the first type
$c_{iw}$ = The marginal costs in the winter for a fisherman of the second type
$FC_i$ = The fixed costs for a fisherman of the first type
$\delta$ = The discounting factor (if $\delta$ is purely economic, then $\delta = 1/(1+r)$, where r = rate of interest)

The fishermen of the second type base their decision on how much to fish by maximizing their profit :

$$TR_j = (P_s - c_{js})^* q_{js} - FC_j \qquad (2.4)$$

$TR_j$ = The revenue of a fisherman of the second type
$c_{js}$ = The marginal costs in the summer for a fisherman of the second type
$FC_j$ = The fixed costs for a fisherman of the second type

The P intercepts of the demand curves are greater than the marginal costs in order to allow positive production, i.e. $c_{is}$, $c_{js} < A$ and $c_{iw} < B$.

When these profit functions are maximized the quantity produced by each fisherman of the first type in the summer is a function of the demand in summer, the constant f, his own marginal costs in the summer, how much the other fishermen of the first type will fish in the summer, how much the fishermen of the other type will fish in the summer and the discounted value of his production in the winter. This is the reaction function, i.e the function which describes what would be the best response for a fisherman to a quantity produced by another fisherman.

In a Nash equilibrium formed by identical fishermen all fishermen of the same type produce the same quantity (e.g. Salant et al. 1983). Therefore the reaction function of a single fisherman can be simplified by noting that in the equilibrium all the $q_i$s are identical and therefore $\Sigma q_i = n^* q_i$ . Because the same is true for the fishermen of the second type the quantity the group produces is m times the production of one fisherman ($\Sigma q_j = m^* q_j$).

The reaction function for a fisherman of the first type is :

$$q_{is} = \{[(n-1)\,bA - \delta fB] - [(n+1)\,b]\,c_{is} + \delta f c_{iw} - [(n+1)\,ab - \delta f^2]\,mq_{js}\}/C1\,, \qquad (2.5)$$

where $$C1 = [(n+1)^{2*} a^* b - \delta^* n^* f^2]$$

1. The constant f can be interpreted as the determining the amount of frozen or otherwise stored fish or fish products. An alternative interpretation is that it reflects consumer behavior which depends on quantities or prices in the first period.

In the same way the reaction function for a fisherman of the second type is :

$$q_{js} = [A - n*a*q_{is} - c_{js}] / [(m + 1)*a] \tag{2.6}$$

### 2.1.1 Optimal individual choice

Using the equations 2.1 - 2.4 and first calculating the reaction functions for a fisherman of each type, then taking into account that all the fishermen of the same type have to produce an equal amount in a Nash equilibrium, the optimum is found by substituting the reaction functions for a fisherman of one type into that of a fisherman of the other type. This will give the optimal production in summer and winter and the corresponding prices. By subsituting the results into the revenue functions (2.3) and (2.4) the profits can be derived as functions of $c_{js}$, $c_{is}$, $c_{iw}$, interaction terms and fixed costs (see appendix).

### 2.1.2 Optimal individual choice with capacity constraints on the more efficient type of fishermen

If the fishermen of the second type have a capacity constraint, they cannot fish more than the quantity $\hat{q}$. Such a situtation may arise if unsubstitutable production resources are limited, for example the places where the gear can be used, or if scale effects are such that costs increase drastically with an expansion of scale. This appears to be a reasonable approximation in the Finnish herring fishery where small scale gillnetters and trap netters can be seen to represent this type of fishing.

The reaction function (2.6) will now take the form :

$$\begin{aligned} q_{js} &= [A - n*a*q_{is} - c_{js}] / [(m + 1)*a], \quad && q_{js} < \hat{q} \\ &= \hat{q} \quad , && q_{js} \geq \hat{q} \end{aligned} \tag{2.7}$$

When the constraint is binding ($q_{js} \leq \hat{q}$) the optimal production of the fisherman of the first type is obtained directly by inserting $\hat{q}$ for $q_{js}$ in equation (2.5).

### *2.2 Collusions among fishermen*

Due to the nature of the fishing operations of the fishermen of the second type we assume that these fishermen have lower marginal costs in the summer than the fishermen of the first type (i.e $c_{js} < c_{is}$) and all know this. From this follows that the greatest joint profit is obtained when all the fishermen of the second type can produce their full capacity $q_j$ and the fishermen of the second type decide the price according to the residual-demand $Q^R_s = Q_s - m* \hat{q}_j$, where Q indicates total quantities. To achieve such a complete monopoly there has to be an agreement on transfer of revenues between fishermen in order to share the revenues equally. Such a monopoly's objective function is

$$TR = (P_s - c_{js})* m* \hat{q} + (P_s - c_{is})\, Q^R_s + \delta *(P_w - c_{iw})* Q_w - mFC_j - nFC_i \tag{2.8}$$

The assumption of revenue transfer is, however, highly unrealistic in a fishery such as that of the Finnish herring fishery. Therefore we will not consider the complete monopoly further. Instead we turn to a more realistic situation in which the more efficient type of fishermen simply form a constraint experienced by the other type of fishermen. They can respond to this constraint by forming a collusion among themselves or act as individual fishermen. In order to be able to treat the production of the other type of fishermen as a constant constraint it is necessary that the capacity constraint of the second group is so low that the optimal response is to produce the maximum quantity $m*\hat{q}$ for a wide range of quantity strategies by the first group. We thus assume [2] that the reaction curves always cross where $q_{js} = \hat{q}$.

2. The solution under the condition of a non binding quantity constraint can be obtained by setting n = 1 (=collusion) in the appendix and setting the condition (2.7) such that it is not binding.

With the additional assumptions we now get for the fishermen of the first type the following objective function which sets the amounts to be produced [3] after optimization :

$$TR = (P_s - c_{is})^* Q_s^R + \delta^*(P_w - c_{iw})^* Q_w - n^* FC_i \quad (2.9)$$

Each fisherman receives an equal share (i.e. $TR_1 = TR/n$) of the total revenue of the collusion.

$Q^R_s$ is obtained from the definition and by subtituting the prices from (2.1) and (2.2) quantities for each fisherman can be obtained simply by dividing the resulting $Q^R_s$ and $Q_w$ with n. The demand functions (2.1 and 2.2) give the corresponding prices and hence the revenues for each fisherman. The revenue per fisherman will always be higher in the case of a complete collusion than in the case of non-cooperation.

The collusion does not, however, represent a Nash equilibrium in this case. A single fisherman will increase his revenue if he leaves the collusion when everybody else stays in [4]. To see this we examine the difference between the total revenue of a single outsider and the individual revenue in a complete collusion :

$$D_{TR} = - C2 * C3 / C4, \quad (2.10)$$

where $C2 = 9\,ab - 2f^2\delta - 4\,abn + f^2\delta n$

$C3 = b\,(A - c_{ik})^2 + a\delta\,(B - c_{it})^2 - f\delta\,[(B - c_{it})\,(A - c_{ik})]$
$+ (A - c_{ik})\,(f^2\delta m\hat{q} - 2\,abm\hat{q}) - af\delta m\hat{q}\,(B - c_{it}) + a^2b\,(m\hat{q})^2$

$C4 = (-4\,ab + f^2\delta) * (-9\,ab + 2f^2\delta) * n$

The necessary conditions for this expression to be greater than zero is that $n \geq 3$ and that the assumptions about a,b,f,$c_{ik}$ and $c_{it}$ hold (see section 2). In addition the expression is quadratic in $m\hat{q}$. The capacity constraint on the second type of fishermen will thus affect the profitability of leaving. We can show, however, that the $D_{TR} > 0$ for all $m\hat{q}$. Therefore it is always profitable for a single fisherman to leave the collusion, and as identical fishermen will make the same decision the collusion breakes down to complete competition. We do not consider here the possibility of a certain fraction of the fishermen remaining in the collusion by separate decisions of insiders and outsiders as analyzed by Salant et al. (1983). In order to achieve this additional assumptions have to be made on differences in decision making between insiders and outsiders.

## 3. COLLUSIONS WITH SUBIDIZED PRICES

### *3.1 Price subsidy on all fish*

When price subsidies (s per quantity) is paid on all fish to any fisherman it is equal to a reduction of all marginal costs by a fixed amount. The fishermen of the second type will experience an increase in their revenue, but the increase will depend on how much the fishermen of the first type increase their production. The increase in production will in turn depend on whether the fishermen form a collusion or act as independent producers.

The objective function of the fishermen of the first type is now

$$max\ TR = (P_K + s - c_{IK})^* q_{iK} + \delta^*(P_T + s - c_{IT})^* q_{iT} - FC_i \quad (3.1)$$

3. When the fishermen act like a monopoly price and quantity setting is equal. We will base our argument on quantity setting for sake of simplicity although for example the Finnish herring negotiations aim at fixing a price.
4. In order to find the profit of the outsider the optimization is repeated in the form of a two actor game, the outsider against the collusion. This will change both total quantities and prices.

The maximization gives the optimal quantities, prices and revenues. Again we can show that a complete collusion is profitable, and more profitable than one without a subsidy. As above the difference in total revenue between a single outsider and the insiders can be calculated. The expression is analogous to that in (2.10), i.e.

$$D_{TR(s)} = - C2 * (C3 + C5) / C4,$$

where $C5 = s\{b\,(2A - 2c_{ik} + s) + a\delta\,(2B - 2c_{it} + s)$
$+ c\delta\,(c_{ik} - A + c_{it} - B - s) + m\hat{q}\,(f^2\delta - 2\,ab - fa\delta)$

The necessary conditions for $D_{TR(s)} > 0$ for all $s > 0$ is that $n \geq 3$ and that the assumptions of the parameters hold as in 2.10. As before $D_{TR(s)}$ is a quadratic function in $m\hat{q}$, but we can show that it is $> 0$ for all $m\hat{q}$ and s. Thus the collusion breakes down as in the case with no subsidies. Quantities will increase and prices go down. This will affect the revenue of the second type of fishermen, although they continue to produce at the level set by their capacity constraint.

### *3.2 Price subsidies paid only on fish sold at the price determined by the collusion*

A pecularity of the Finnish system of price subsidies is that a collusion agrees on a minimum price with buyers and that subsidies are paid only for fish bought at or above the minimum price (Hildén and Mickwitz 1990). In practice this means that subsidies are paid only to those forming the collusion. The total revenue received by the collusion will be determined by the same function as in section 3.1, but the difference in revenue between a single outsider and the individual revenue in a total collusion will change, because the outsider loses the subsidy. We can show that the difference in total revenue is a concave function and that the sign of the first derivative for $s = 0$ will depend on the parameter values. Further we can show that there are levels of subsidies for which the difference in revenue is $< 0$. *Thus this system of subsidization may make the collusion into a Nash equilibrium.*

## 4. SIMULATIONS

The following simulation illustrates our approach on the Finnish herring data. The parameter values, the demand functions and the production functions have not been rigorously estimated and thus the results are given for illustrative purpose only.

With the simulations we aim to answer two basic questions :

i) Is it possible that the collusion which exist in the Finnish herring fishery could arise due to government subsidies ?

ii) What would happen if subsidies were removed completely ?

The simulations are based on the case of subsidies paid to the collusion only, because this has the closest correspondence to the situation in the Finnish herring fishery. In order to be able to investigate the effects of a single outsider, we assume that the collusion is able to react on the production of the outsider as required by the Cournot conjecture. This mechanism is available in the Finnish system for price negotiations, which can be initiated at any stage by any of the contracting parties.

The parameter estimates are based on information on the quantities and prices of herrings sold to be used by the food industry and on guesstimates of the production functions. The following values were used in the simulations :

| **Demand functions** | **Capacity constraint** |
|---|---|
| A = 4000 a = 0.25 | q = 10.5 |
| B = 4200 b = 0.35 f = 0.01 | |
| **Costs** | **Number of fishermen** |
| $FC_i$ = 50000 $c_{is}$ = 2100 $c_{iw}$ = 2400 | n = 80 |
| $FC_j$ = 1000 | m = 250 |

| **Discount rate** | **Subsidy** |
|---|---|
| discount factor $\delta = 1/(1.1)$ | s = 1200 |

According to the simulations the collusion turns into a Nash equilibrium with subsidies > 1089 FIM per ton (Fig. 1). The present subsidy is 1200 FIM per ton, suggesting that the level could be sufficient for creating incentives to remain in a collusion.

With a removal of the subsidy considerable changes would occur. Assuming that the present level of revenue corresponds to a stable situation in an open entry fishery a decrease in revenues would create incentives to leave the fishery. A rough estimate can be obtained by comparing the revenues at the equilibrium points with and without subsidies. The number of fishermen can then be adjusted to correspond to a constant revenue per fisherman of the first type. The second type of fishermen are assumed to continue fishing at the level set by their capacity constraint. The simulations suggest that a removal of the subsidy and the breakdown of the collusion would cause 71 of 80 fishermen to leave the fishery. The removal of the subsidy would somewhat change the price on herring paid by the industry. In winter the price would decrease from 2.66 FIM per kg to 2.57 but in summer the price would increase from 2.14 to 2.23 FIM per kg. The loss of the subsidy means that the fishermen of the second type lose on the change, but they are assumed to remain in the fishery due e.g. to sunken costs. If they would leave as well fewer fishermen of the first type would have to leave. This shows the necessity of analyzing the exit and entry dynamics in the fishery.

## 5. DISCUSSION

The simple Cournot model used in this paper has offered some insights into the role of subsidies by demonstrating that certain systems of subsidization may contribute to the stability of collusions. Stable collusions may emerge even though the game is not based on an indefinite time horizon, which for example Salant et al. (1983) has mentioned as a possible explanation for stable merger.

If a system of subsidies stabilizes collusions the subsidies carry a double benefit to the producers, the subsidy per se and the gains obtained from a monopolistic price setting. In Finland this effect is partly off set by the buyers' organizations, which are able to somewhat adjust the demand curve. A more extensive game illustrating the herring markets in Finland would require the inclusion of the first hand buyers as players. It would also include the small scale fishermen (the second type) as active players and possibly the heterogeneity within the types of fishermen. The result would be an asymmetric game for which no general formulations on factors affecting the formation of collusions appears to be available (e.g. Tirole 1989).

The dynamics of the fish stock has not been included in our investigation because of the present situation on the herring market. Subsidies and collusions could, however, affect the exploitation rates in counter intuitive ways. For example it is possible that the removal of a subsidy would increase the exploitation rates due to the break down of a collusion.

A preliminary sensitivity analysis of the model suggests that the model is sensitive to the choice of parameters. The linear demand functions and costs appear to explain a part of the sensitivity. More realistic simulations would require better estimates of production functions and the demand. These are, however, difficult to obtain, because the history of regulation with fixed prices makes estimation nearly impossible. Yet they are essential for the evaluation of what will happen after the removal of subsidies as demanded by a recent EFTA agreement.

The present analysis has explicitly included a market structure and a crude approximation of the heterogeneity within the fishery. The results show that these features may affect the consequences of a fisheries policy based on subsidies. In addition the comparison of the equilibrium points suggest that knowledge of dynamic changes of market conditions and fleet size will influence any decision on alterations of policy.

**Appendix**

The reaction functions for the case without subsidies and the corresponding functions giving optimum production and prices.

The optimal production for a firm of the firts type is $q^*_{is}$ in the summer and $q^*_{iw}$ in the winter :

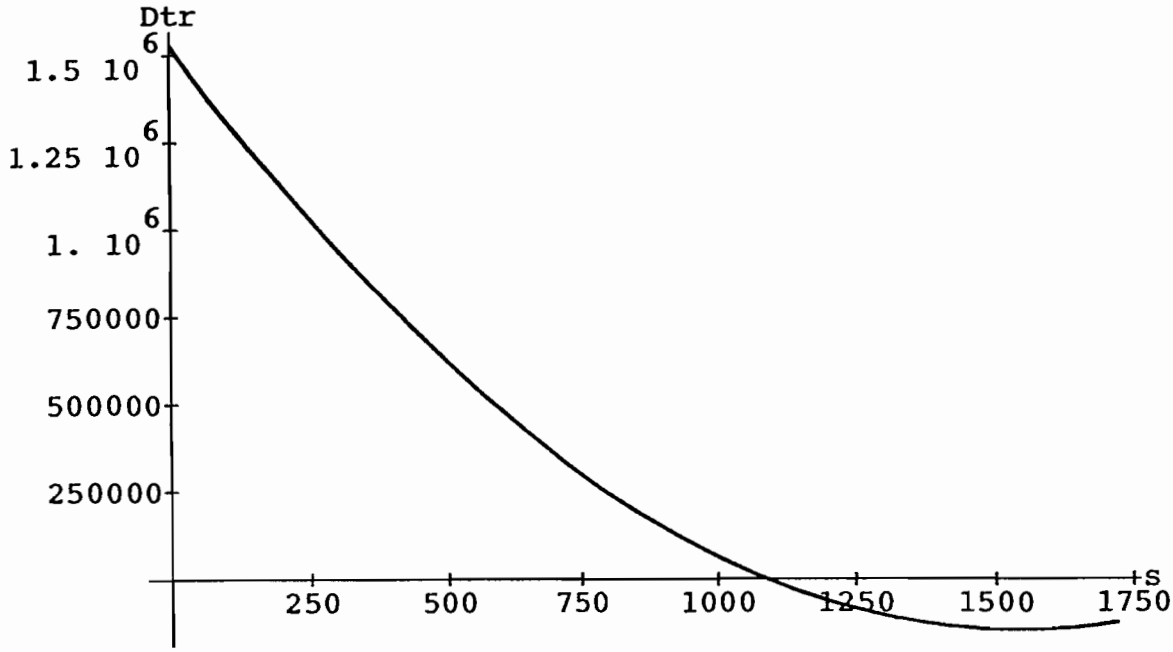
$$q^*_{is} = \frac{(n+1)\,abA + \delta mf^2 A - \delta(m+1)\,afB}{(n+1)^*(n+m+1)\,a^2 b - \delta naf^2} + \frac{[(n+1)\,mab - \delta mf^2]^* c_{js}}{(n+1)^*(n+m1)\,a^2 b - \delta naf^2} - \\ - \frac{[(n+1)^*(m+1)^* b]^* c_{is}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} + \frac{[\delta^*(m+1)^* f]^* c_{jw}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} \quad (A.1)$$

$$q^*_{iw} = \frac{(n+m+1)\,aB - (n+m)\,fA}{(n+1)^*(n+m+1)\,ab - \delta nf^2} + \frac{[m^* f]^* c_{js}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} + \\ + \frac{[n^* f]^* c_{is}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} - \frac{[(n+m+1)^* a]^* c_{iw}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} \quad (A.2)$$

The optimal production for a firm of the second type in the summer ($q^*_{js}$) can be calculated in the same way :

$$q^*_{js} = \frac{(n+1)\,av^* A - \delta nf^2 A + \delta nafB}{(n+1)^*(n+m+1)\,a^2 b - \delta naf^2} - \frac{[(n+1)^2 ab - \delta nf^2]^* c_{js}}{(n+1)^*(n+m+1)\,a^2 b - \delta naf^2} + \\ + \frac{[n^*(n+1)^* b]^* c_{is}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} - \frac{[\delta nf]^* c_{iw}}{(n+1)^*(n+m+1)\,ab - \delta nf^2} \quad (A.3)$$

By substituting n times the optimal production for a fisherman of the firts type (A.1) and m times the optimal production for a fisherman of the second type (A.3) into (2.1). We get the price in the summer :



$$P^*_s = \{(n+1)\,abA - \delta nf^2 A + \delta nafB + \\ + [(n+1)\,mab]^* c_{js} + [n^*(n+1)\,ab]^* c_{iK} - [\delta naf]^* c_{iw}\}/[(n+1)^*(n+m+1)\,ab - \delta nf^2] \quad (A.4)$$

In the same way by using (A.1), (A.2) and (A.3) together with (2.2), we receive :

$$P^*_w = \{(n+m+1)\,abB - (n+m)\,bfA + [mfb]^* c_{js} + [nfb]^* c_{iK} + \\ + [n^*(n+m+1)\,ab - \delta nf^2]^* c_{iT}\}/[(n+1)^*(n+m+1)\,ab - \delta nf^2] \quad (A.5)$$

The total revenues are then easily obtained through subsitution.

**FIGURE 1.**
**THE DIFFERENCE IN PROFIT BETWEEN A SINGLE OUTSIDER AND THE AVERAGE REVENUE PER FISHERMAN (DTR) IN A COMPLETE COLLUSION WHICH RECEIVES SUBSIDIES. SUBSIDIES (S) ARE EXPRESSED IN FIM PER TON HERRING. THE CURVE IS LIMITED BY THE CONSTRAINT $S \geq 0$, $P \geq 0$ AND $Q \geq 0$.**

# Productivity Measurement in Common Property Resource Industries : an Application to the Pacific Coast Trawl Fishery

**Dale Squires** *

National Marine Fisheries Service, Southwest Fisheries Science Center, P.O. Box 271, La Jolla, California 92038, USA

ABSTRACT

*This study measures total factor productivity in industries that exploit resources held in common. Particular attention is paid to the valuation and specification of in situ common property resources in a neoclassical production technology, catchability of the resource, and variations in economic capacity utilization. An empirical analysis of the open-access Pacific coast trawl fishing industry demonstrates that disentangling the productivity residual from changes in resource abundance, its catchability, and variations in capacity utilization hones the productivity residual to finer precision, lowering mean productivity growth by about half. Removing biological noise from highly variable resources is also important. The results are related to a program limiting the number of vessels and can contribute to sustainable resource management whenever resources are held in common.*

## 1. INTRODUCTION

Productivity measurement in industries utilizing common property natural resources faces the thorny problem of accounting for the nonpriced contributions from these resources. When changes in abundance of the resource stock are not disentangled from measures of productivity or technical progress, results will be biased.

* The comments of an anonymous referee, Kevin Carlson, Jon Conrad, Chris Dewees, Susan Hanna, Tom Hertel, Sam Herrick, Jim Kirkley, Alec MacCall, Gordon Munro, Sam Pooley, Robert Pindyck, James Poterba, Anthony Scott, and Jim Wilen on an earlier version of this manuscript are gratefully acknowledged. The author is also grateful to Bob Francis, Jim Golden, Frank Henry, Joe Hightower, Dan Itoh, Larry Jacobsen, Bill Lenarz, Alec MacCall, Rick Star, Jack Taggart, and Pat Tomlinson for assistance with the population dynamics, and to Ralph Brown and Larry Schock, two commercial fishermen for insights into technical change. The authors remain responsible for any errors. The results are not necessarily those of the National Marine Fisheries Service.

The crucial factors for studies of productivity or technical progress in these industries are the proper specification and valuation of the common property resources in a production technology and the related issue of market failure and external diseconomies to firms. In turn, these factors depend upon : the structure of property or access rights ; the level of aggregation of the analysis (the firm or society/industry) ; and the stock-flow relationship between the resource stock and its extractive activity. Smith and Krutilla (1982), Smith (1980), Brown and Field (1978) and Fisher (1979) touched upon these concerns, but they have yet to be fully developed.

This study develops a framework for measuring total factor productivity (hereafter TFP) in industries that exploit renewable resources held in common, paying particular attention to their valuation and specification in a neoclassical production technology. The method of growth accounting and economic index numbers is modified to accommodate the resource and to measure productivity growth in the Pacific coast trawl fishery. Accounting for changes in resource abundance, its catchability, and capacity utilization hones the productivity residual to finer precision, lowering it by about half.

## 2. SPECIFICATION AND VALUATION OF THE RESOURCE STOCK

Common property natural resources have traditionally been treated like any other input in a neoclassical production technology. Beginning with Scott (1954), the common property resource stock entered the production process as a factor of production and was treated as an asset, particularly as a stock of capital. This approach was applied to both renewable and nonrenewable resources.

In an analysis rooted in the theory of the firm, it is inappropriate to treat a common property resource stock as a conventional input. Instead, this stock is specified as a technological constraint on the individual firm's stock-flow technology because the stock's abundance affects the production environment within which firms operate but remains beyond the control of any individual firm. That is, conventional inputs such as capital, labor, and energy are organized conditional upon expected resource stock abundance levels to generate the extractive flow. Increases (decreases) in resource abundance then shift the production technology, increasing (decreasing) the rate of extractive flow for any given input bundle. McFadden (1978) develops this approach within the framework of the firm's production possibilities set, treating environmental parameters (such as resource abundance) similar to disembodied technical change. Also, the resource stock places a maximum limit upon the extraction rate.

Resource abundance as a technology shift parameter can be specified in the firm's neoclassical production function. This function F expresses the stock-flow relationship between the resource stock and the extractive activity at a given time period. F takes the vector of inputs X and applies it to the resource stock to extract flow Y, conditional upon the state of technical knowledge t and resource stock abundance level, B. It is written : $Y = F(X[V]\ t,B)$.

An increase in the size of B allows an increase in the flow rate of resource extraction for any given X and t, so that $\delta F/\delta B > 0$. Similarly, technical progress shifts F, given X and t, so that $\delta F/\delta t > 0$. Thus both the abundance of the resource stock and disembodied technological change may be treated as technology shift parameters.

Gordon (1954) treated fish abundance as a technological constraint in his seminal article on marine fisheries as common property resource industries. While this approach does not preclude managing the fishery *as if* the resource stock was an asset, the framework does properly specify the resource stock in the same manner as any other environmental parameter, as a technological constraint, instead of an input under the control of individual firms.

Proper valuation of the common-property resource stock depends upon the specific property right structure governing its use. Under competitive open-access conditions, the firm's utilization decision for the resource is not endogenous, and each firm ignores the effects of its production upon the resource stock. Each firm instead behaves as if the resource has a zero user cost, because the effect of a unit change in resource abundance on the open-access firm's profits is zero due to rent dissipation (Gordon ; Smith, 1969 ; Capalbo, 1986). The firm's marginal costs and the market prices it faces include only the extraction component and not the user cost component (the latter which is zero).

In contrast, a sole owner must explicitly contend with the user cost, because the resource utilization decision is now endogenous through the choice of extraction rate and input usage (Capalbo ; Smith). Social costs associated with the resource externality are now private costs to the firm, and along with extraction costs, factor into the firm's optimization

problem (Smith). Market prices include the marginal user cost of the resource as a component of the full extraction costs. Similarly, the user cost is explicitly considered as a cost when property rights are not assigned but the emphasis is given to social evaluation of productivity growth.

## 3. THE FIRM'S OPTIMIZATION PROBLEM AND PRODUCTIVITY MEASURES

Specification of the firm's profit maximization problem depends upon the nature of property or access rights (or aggregation level). Both sole owner and open access *in situ* common property resources are considered. Following standard practice (cf. Clark), a Schaefer (1957) type production technology is assumed, where each vessel's catch per unit of time is proportional to the resource stock, and its costs are inversely proportional to the resource stock. Non-capital costs and inputs are distinguished from capital to facilitate capital's role in a later discussion of capacity utilization (CU), but full static equilibrium in all inputs is initially allowed to not confound the discussion of property rights with that of CU. Only the germane results are given, with full development in Squires (1991).

The Lagrangian for the optimization problem of a sole owner (or society) is :

$$\max_{Y_t,\, K_t,\, B_t} L = \{ P_t Y_t - G(Y_t, K_t, W_{jt}, B_t t) - W_{Kt}K_t \} + \phi_1 [B_t - Y_t] + \phi_2 [B_{t+1} - B_t - h(B_t, Y_t, E_t, U_t)], \quad (1)$$

where $P_t$ is the product price, $W_{jt}$ is the price of the $j^{th}$ variable input $X_{jt}$, $W_{Kt}$ is the rental or services price of capital $K_t$, t indexes the state of technical progress (assumed Hick's-neutral and disembodied), $B_t$ is the resource stock, $h(\cdot)$ is the biological growth function, $Y_t$ is the current resource extraction rate, $G(Y_t,K_t,W_t,B_t,t)$ is the variable cost function for the optimal combination of variable inputs, where $\delta G/\delta B < 0$, and $\phi_i$ is the Lagrangian multiplier for constraint i.

The first constraint indicates that the extractive flow from the resource cannot exceed the resource stock itself. The second represents discrete-time growth of the resource stock. Abundance in time t is determined by its level in the previous time period ($B_{t-1}$), its growth function (h), the resource extraction rate ($Y_t$), environmental parameters ($E_t$ ), and any public regulations ($U_t$). Not only are $Y_t$ and $K_t$ decision variables to the sole owner, but so is $B_t$ via the choice of current extraction rate $Y_t$ and the long-run planning decision for $K_t$ (Capalbo ; Smith). All *ex-ante* expectations are assumed realized *ex-post.*

The first-order conditions for an interior solution are :

$$L_Y = P_t - G_Y - \phi_1 - \phi_2 h_Y = 0 \quad \text{or} \quad P_t - \phi_1 - \phi_2 h_Y = G_Y \quad (2a)$$

$$L_K = -W_K - G_K = 0, \quad \text{or} \quad W_K = -G_K \quad (2b)$$

$$L_{\phi 1} = B_t - Y_t = 0, \quad \text{or} \quad B_t = Y_t, \quad (2c)$$

$$L_{\phi 2} = B_{t+1} - B_t - h(B_t, Y_t, E_t, U_t) = 0, \quad \text{or} \quad B_{t+1} - B_t = h(B_t, Y_t, E_t, U_t), \quad (2d)$$

$$L_B = -G_B + \phi_1 - \phi_2[1 + h_B] = 0 \quad \text{or} \quad -G_B = -\phi_1 + \phi_2[1 + h_B]. \quad (2e)$$

Condition (2a) states that the harvest rate should be selected such that marginal extraction cost $G_Y$ (= $\delta G/\delta Y$) equals product price less the marginal value of non-extinction $\phi_1$ less the marginal rent from additional fish recruits $\phi_2$ times the marginal impact of the current harvest rate on the resource stock $h_Y$ (=$\delta h/\delta Y$). Extinction is generally irrelevant and $\phi_1$ may be set equal to 0. Sole ownership implies $\phi_2 > 0$, so from (2a), $P_t = G_Y + \phi_2 h_Y$ .
(2b) gives the reduction in variable costs, $- G_K = \delta G/\delta K$, from using one more unit of capital to produce a given output, or the shadow price of capital.

Condition (2e) demonstrates two benefits from a unit of resource in place at time t (with $\phi_1 = 0$) : (1) harvesting costs are lowered and, (2) additional value accrues from future growth of the resource stock (Clark). These two benefits form the user cost, i.e., the opportunity cost to the user of taking a unit of the resource in the present period. Because the analysis is positive, concerned with measuring productivity growth, the stationary state equilibrium conditions for the stock in a normative analysis are not considered.

The continuous time Divisia index of total factor productivity using nonparametric growth accounting is :

$$-\frac{\delta \ln C}{\delta t} = \frac{[P - \phi_2 h_Y] Y}{C}\frac{\dot{Y}}{Y} - \Sigma_j \frac{W_j X_j}{C}\frac{\dot{X}_j}{X_j} - \frac{W_K K}{C}\frac{\dot{K}}{K} - \frac{\phi_2[1 + h_B] B}{C}\frac{\dot{B}}{B}, \tag{3}$$

where $C = \Sigma_j W_j X_j + W_K K + \phi_2 h_Y Y + \phi_2[1+h_B]B = PY$ with linear homogeneity, and the dots over variables represent time derivatives.

Equation (3) shows TFP measured as the residual after allocating the growth rate of output among changes in variable inputs, capital, and resource abundance, the latter specified as Hick's-neutral and disembodied. The user cost of the marginal unit of the *in situ* resource, $\phi_2$, is explicitly considered in this sole owner problem.

In the individual competitive firm's profit maximization problem, $B_t$ is not a decision variable, so that $h_B$ is not relevant, and each firm ignores $\phi_2$ . Only indirectly through $h(B_t,Y_t,E_t,U_t)$ do changes in firms' resource extraction rates affect the resource stock level. The productivity measure is a special case of (3) :

$$-\frac{\delta \ln C}{\delta t} = \frac{\dot{Y}}{Y} - \Sigma_j \frac{W_j X_j}{X}\frac{\dot{X}}{X_j} - \frac{W_K K}{C}\frac{\dot{K}}{K} - \frac{\dot{B}}{B} \tag{4}$$

where $C = \Sigma_j W_j X_j + W_K K = PY$ under constant returns to scale.

The productivity residual is biased without disentangling variations in $B_t$. In contrast to the sole owner, because $B_t$ is not a decision variable to firms and $\phi_2 = 0$, proportional changes in abundance are simply pared away from the conventional productivity residual without weighting by cost shares in this positive analysis.

Regulation of a competitive open-access fishery can either develop property or access rights or impose production constraints. This section considers constraints on the extraction process for the competitive open-access fishery, since rights-based regulation is related to the sole owner problem. Market failure remains because rights are underdeveloped, and the analysis remains firm-level and positive rather than normative.

Under a catch quota, $Y^*$, the constraint $Y_t \leq Y^*$ is added to equations (1) and (2) (Denny et. al. 1981). The Lagrangian for a binding constraint, $\phi_Y$, is the virtual price of the quota (Rothbarth 1941) and the unit quota rent is $P_t - \phi_Y$. The first-order condition in the open-access problem is now : $P_t - \phi_Y = G_Y$ ; vessels adjust catch rates until the unit quota rent equals marginal extraction cost. Alternatively, the cost of market failure can be imposed on firms by a landings tax $\Gamma$. (2a) is now : $P_t = G_Y + \Gamma$ ; firms adjust the catch rate until price equals private marginal extraction cost plus tax.

With a binding regulation $K_t \leq K^*$ , $\phi_K > 0$, production costs increase, and the net services price of capital becomes $W_K + \phi_K$ .

Changes in the size of $B_t$ do not affect productivity measures as directly as indicated in equations (3) and (4). An input bundle often catches an increasing proportion of the residual resource stock as $B_t$ declines, due to the concentrating or schooling behavior of many fish species and the nature of the fishing technology (MacCall, 1990). As $B_t$ decreases in size, so does its spatial distribution, but the density of fish over an area or school size changes little. Fishing firms can quickly locate the remainder, even of a heavily depleted stock, and harvest at rates similar to those of a higher stock level. Thus the "catchability" of stock is not directly related to $B_t$'s size and must be adjusted. Following standard procedures (MacCall, 1976), the catchability coefficient weighting $B_t$'s abundance is a power function (see below).

Productivity measures are biased when output growth comes from changes in capacity utilization of quasi-fixed factors (CU) along with those of variable factors and productivity (Berndt and Fuss) and common property resource abundance. Altering the value and not the quantity of the quasi-fixed factors adjusts the productivity residual for variation in CU with growth accounting (Berndt and Fuss). Under constant returns to scale for the unregulated competitive open-access fishery,

$P_t Y_t = G(Y_t,K_t,W_t,B_t,t) + Z_{Kt}K_t = \Sigma_j W_{jt}X_{jt} + Z_{Kt}K_t$.

Rearranging : $Z_{Kt} = [P_t Y_t - G(\cdot)]/K_t = [P_t Y_t - \Sigma_j W_{jt}X_{jt}]/K_t$. The quasi-rent $Z_{Kt}$ is the residual income not accruing to variable inputs per unit of capital stock (Hulten).

## 4. THE INDUSTRY, DATA, AND INDEX CONSTRUCTION

The Pacific coast trawl fishery is comprised of vessels in Washington, Oregon, and California harvesting a wide variety of groundfish and pelagic fish species and pink shrimp. The three important trawl gear are groundfish (bottom or roller), shrimp, and midwater, the latter used by vessels making at-sea deliveries of pelagic Pacific whiting in a joint venture with foreign fleets ; production between gears is nonjoint. Vessels flow between the groundfish and shrimp trawl sectors with the rise and fall of shrimp abundance. Larger vessels may also fish in Alaskan waters.

A more complete description of the industry and data are available in *The Rand Journal of Economics*, vol 23, n° 2, 1992.

### *4.1 Data*

The analysis covers 1981-1989, the only years with comprehensive economic and biological data. Squires (1988) gives details on all data and index construction except the biological, which are reported in Squires (1991). Electronic spreadsheets with all calculations and data or summary tables of the raw data are available upon request. The output indices require pounds landed and revenues by US vessels at ports in Washington, Oregon, and California by species. Revenue and landings data are from the PacFIN Management Data Base (PacFIN) of the National Marine Fisheries Service (NMFS). All values are deflated by the GNP implicit deflator.

By 1989, sablefish production faced a consistently binding quota. Hence 1989 sablefish output was valued by P-$\phi_Y$ , its implicit unit rent, where $\phi_Y$ was its virtual price. Coastwide estimates of $\phi_Y$ were unavailable, but based on a study of a Northern California trawl fishery (Squires 1990), $\phi_Y$ was set at 68 % of the product price.

### *4.2 Tornqvist productivity index*

A discrete-time approximation to the continuous Divisia index of (4) is given by the Tornqvist approximation. This index for an unregulated open-access fishery allowing for variations in CU and resource abundance becomes :

$$\begin{aligned} \ln (TFP_t / TFP_{t-1}) = {} & 0.5\, \Sigma_i (R_{it} + R_{i,t-1}) \ln (Y_{it} / Y_{i,t-1}) \\ & - 0.5\, \Sigma_j (S_{jt} + S_{j,t-1}) \ln (X_{jt} / X_{j,t-1}) \\ & - 0.5\, (S_{Kt} + S_{K,t-1}) \ln (K_t / K_{t-1}) - \ln (B_t / B_{t-1}), \end{aligned} \tag{5}$$

where B is the composite index of resource abundance, $R_i = (P_i Y_i) / (\Sigma_i P_i Y_i)$ is the revenue share for output i, $S_j = (W_j X_j) / (\Sigma_i P_i Y_i)$ is the cost share for variable input $X_j$, and $S_K = (Z_K K) / (\Sigma_i P_i Y_i)$ is the capital cost share allowing for variations in CU.

## 5. EMPIRICAL RESULTS

The empirical results for the open-access Pacific coast trawl fishery demonstrate the importance of adjusting the multifactor productivity residual for variations in : (1) capacity utilization ; (2) resource abundance ; and (3) the catchability coefficient. Failure to make these adjustments biases productivity measures.

Biomass growth (Table 1) indicates generally declining Pacific whiting biomass, punctured by occasional increases, reflecting young age at maturity and the sporadic recruitment of strong year classes of juvenile fish into the fishable stock. The unstable pink shrimp growth reflects the unstable growth rate due to fluctuations in environmental parameters. The overall biomass index is strongly influenced by whiting and pink shrimp due to their large, fluctuating biomasses and revenue shares.

The rockfish, flatfish, and sablefish growth rates (Table 1) reflect the steady, prolonged decline in biomass due to unsustainable catch rates (Table 3) greater than the slow net growth of the biomass (this reflects long lives, slow growth and steady recruitment rates).

The late 1970s and early 1980s were generally years with CU > 1 (Table 6). Production moderately expanded (Table 3) because the domestic fleet no longer faced foreign competition following the MFCMA of 1977 (which restricted foreign fishing and created exclusive fisheries zones out to 200 miles) and because several resource stocks (particularly rockfish) were harvested at rates exceeding maximum sustainable yield (MSY). New vessels were constructed, increasing fleet size and aggregate input use (Table 7). Around late 1982, pink shrimp virtually disappeared due to El Nino (which substantially altered ocean temperature) and output and input prices declined (Table 8). The quasi-rent to capital was less than the capital services price, i.e. $Z_K < W_K$, and CU < 1 (Table 6). Bankruptcies increased and a number of vessels were idled or left the fleet (Table 7), transferring activities to Alaska, sunk, or burnt ; disinvestment occurred with a lag.

Around 1985-1986, overall biomass began to rebuild, primarily from a dramatic resurgence of the high-priced pink shrimp as El Nino resided and growth in Pacific whiting biomass (Table 1). Real fuel prices and interest rates also dropped, while real output prices for most species rose, except for a dip in 1988 (Table 8). Hence, $Z_K > W_K$ and CU > 1, signalling investment incentives (Table 6). Fleet size and aggregate input (Table 7) responded, expanding, albeit only with a lag, and jumped by 6.3 % in 1987.

In 1988-89, the overall biomass slightly declined due to a plunge in rockfish abundance beginning in 1987 and a decline in Pacific whiting (Table 1), and output prices dropped in 1988 but climbed in 1989 (Table 8). $Z_K$ fell by 36 % but remained above $W_K$, CU remained above one, and the fleet size remained stable.

In sum, CU signaled private investment incentives for most of the decade, but the fishery was overcapitalized from a social perspective due to the open-access externality, and harvesting rates were often greater than MSY. By the decade's end, most resources had fallen to near or below MSY levels with stable or declining trends.

Table 5 reports total factor productivity measures. There are no adjustments for changes in resource abundance in columns (1) or (2). Column (1) measures productivity assuming full equilibrium of capital. The combined effect of technical progress and resource abundance changes in column (1) indicates two cycles of declines followed by increases in productivity. Column (2), which adjusts for CU variations, shows reduced productivity growth, dampened fluctuations in growth rates, and a more complex pattern.

Excluding resource growth biases productivity measures. Column (3) of Table 5 reports TFP incorporating variations in CU and biomass, but not catchability. In years of declining biomass, such as 1981-1984 and 1988-1989, TFP is otherwise understated. Similarly, when biomass increased, such as during 1985-1987, the greater ease of finding and catching fish, unless accounted for in this stock-flow production technology, overstates TFP growth. Annual productivity growth can also reverse signs unless resource growth is included.

Adjusting the biomass estimates for variations in catchability in column (4) of Table 5 generally dampens the effects of changes in resource abundance upon productivity growth and its year-to-year fluctuations. This enhanced stability follows from the density dependent habitat selection of fish as discussed above. Mean productivity growth is about half after the full set of corrections.

Productivity growth over the decade averaged a disappointing 0.65 %. The productivity growth rate over 1981-84, years of declining biomass in all species, averaged a strong 5.33 %. Growth averaged -2.15 % over 1985-89, years of rising overall biomass (or modest declines but nonetheless falling for all species except shrimp).

Productivity in this stock-flow technology ostensibly rose when overall output growth was unsustainable but fell under sustainable harvesting rates. More accurately, however, exploitation rates for most species except shrimp were unsustainable in most years. Growth in productivity and overall biomass were instead driven by, and inversely related to, the large rises and falls in shrimp biomass (responding to environmental conditions), and to a lesser extent, whiting biomass (due to young age at maturity and sporadic recruitment of large year classes). High revenue shares gave emphasis. Yet their biomass growth and variation, particularly for shrimp, are largely dependent upon biological and environmental processes beyond the control of regulators or industry. Firms suffer low apparent productivity growth because of the large biological noise and the corresponding difficulty in organizing efficient harvesting.

To assess productivity growth without the swamping effect from the whiting and shrimp biomasses, all indices were recalculated for only groundfish vessels, the heart of the Pacific trawl fleet. Shrimp biomass was excluded entirely, while

whiting biomass was included but weighted by a revenue share excluding joint venture trawlers (groundfish trawlers catch some whiting). Table 9 reports the chain indices and growth rates for productivity, aggregate output and input, and biomass. Productivity growth averaged 2.79 % and the annual variation declined considerably as the biological noise (from pink shrimp and joint venture-caught whiting) was removed from the system. Productivity growth also became consistently positive from mid-decade, except in 1987 when CU and aggregate input surged. These changes followed from exiting vessels transferring to Alaska and the resurging shrimp biomass, both of which attracted vessels out of groundfishing. The rate of groundfish biomass decline also slowed (Table 9). Productivity also grew from extensive technical progress (discussed below), even in the face of excessive input use under open access.

The productivity growth rate in both the entire fleet and solely groundfish trawlers displayed considerable annual variation. The ability of mobile vessels to rapidly enter and exit an open-access fishery and switch gear, coupled with fluctuations in resource abundance, generated sharp productivity swings.

License limitation programs, which limit the number of vessels, are plagued by the continued increase in productivity and consequent pressures on the resource, even though vessel numbers have been capped. Programs to remove vessels dampen harvesting pressures, but continued productivity growth of the remaining vessels gives countervailing pressures. A recent license limitation program for groundfish vessels could be hampered by productivity growth without compensating vessel reductions, or by eligible shrimp vessels reentering the groundfish sector.

TABLE 1.
PERCENTAGE ANNUAL GROWTH RATES OF BIOMASSES

| | Species: No catchability correction | | | | | Aggregate | | |
|---|---|---|---|---|---|---|---|---|
| Year | Flatfish | Rockfish | Sablefish | Whiting | Shrimp | (1) | (2) | (3) |
| 1982 | -1.05 | -9.90 | -0.07 | 7.15 | -10.42 | -5.84 | -2.92 | -4.78 |
| 1983 | 2.29 | -13.42 | -0.24 | -1.20 | -15.59 | -14.41 | -7.21 | -8.91 |
| 1984 | -4.13 | -10.97 | -0.33 | -0.59 | -4.31 | -9.75 | -4.88 | -6.87 |
| 1985 | -1.00 | -5.92 | -0.49 | -0.65 | 15.98 | 7.68 | 3.84 | 5.65 |
| 1986 | -0.98 | -4.05 | -0.63 | 4.75 | 27.27 | 22.52 | 11.26 | 15.02 |
| 1987 | -0.19 | -5.58 | -0.41 | -1.37 | 11.09 | 6.17 | 3.09 | 4.70 |
| 1988 | -0.52 | -9.84 | -0.18 | -2.86 | 1.91 | -3.51 | -1.75 | -1.67 |
| 1989 | -0.66 | -1.60 | -0.23 | -3.44 | 3.56 | -0.97 | -0.48 | -0.22 |
| Mean | -0.78 | -7.66 | -0.32 | 0.22 | 3.69 | 0.24 | 0.12 | 0.37 |

Note: (1) No catchability correction for aggregate biomass index
(2) Uniform square root catchability correction
(3) Differential power catchability correction (see text)

Note: Pacific trawl fleet includes groundfish, shrimp, and midwater joint venture trawl vessels

TABLE 5.
TOTAL FACTOR PRODUCTIVITY GROWTH IN THE PACIFIC COAST TRAWL FISHERY, 1981–1989

| Year | No correction (1) | CU correction (2) | CU & biomass correction (3) | Full correction (4) |
|---|---|---|---|---|
| 1982 | -8.139 | -6.538 | -0.700 | -1.755 |
| 1983 | -5.028 | -3.889 | 10.526 | 5.017 |
| 1984 | 9.623 | 5.871 | 15.622 | 12.737 |
| 1985 | 2.967 | 7.763 | -6.902 | -4.873 |
| 1986 | 14.163 | 9.928 | -12.589 | -5.089 |
| 1987 | -8.916 | -3.988 | -10.161 | -8.689 |
| 1988 | 2.255 | 7.662 | 11.171 | 9.332 |
| 1989 | 1.653 | -1.664 | -0.697 | -1.444 |
| Mean | 1.072 | 1.020 | 0.783 | 0.654 |

Columns: (1) Long-run equilibrium in capital and no biomass correction
(2) Correction for variation in capacity utilization (CU) but not biomass
(3) Correction for variation in capacity utilization (CU) and biomass but not for variation in catchability coefficient
(4) Correction for variation in capacity utilization and biomass, and variability in catchability coefficient.
Note: Calculated by Tornqvist bilateral chain indices
Percentage annual growth rate

TABLE 6.
CAPITAL PRICES AND CAPACITY UTILIZATION PER VESSEL

| Year | Capital services price ($W_K$) | Quasi-rent of capital ($Z_K$) | Capacity utilization |
|---|---|---|---|
| 1981 | 60,535 | 79,487 | CU > 1 |
| 1982 | 62,859 | 84,067 | CU > 1 |
| 1983 | 55,405 | 53,041 | CU < 1 |
| 1984 | 56,082 | 51,096 | CU < 1 |
| 1985 | 53,501 | 38,002 | CU < 1 |
| 1986 | 47,628 | 82,228 | CU > 1 |
| 1987 | 56,728 | 116,133 | CU > 1 |
| 1988 | 57,535 | 77,486 | CU > 1 |
| 1989 | 55,437 | 96,756 | CU > 1 |

Note: $1981. Mean per vessel values.

TABLE 7.
AGGREGATE INPUT GROWTH RATES

| Year | Washington | Oregon | N. Calif. | C. Calif. | Fleet Aggregate |
|---|---|---|---|---|---|
| 1982 | -10.30 | 2.53 | 20.52 | 3.27 | 7.12 |
| 1983 | 4.25 | 3.38 | -11.15 | -10.93 | 0.14 |
| 1984 | -9.40 | -7.48 | -2.49 | -9.11 | -7.24 |
| 1985 | -2.45 | -6.87 | 5.90 | 19.81 | 0.67 |
| 1986 | 4.93 | 1.91 | -14.76 | -34.99 | -2.75 |
| 1987 | 5.70 | 9.50 | 5.21 | -28.40 | 6.33 |
| 1988 | 6.91 | -7.55 | -3.96 | -8.41 | -4.00 |
| 1989 | -2.61 | 8.85 | 0.02 | -0.40 | 4.65 |
| Mean | -0.37 | 0.53 | -0.09 | -4.96 | 0.61 |

Note: Tornqvist bilateral chain index. Percentage growth rate. Full static equilibrium of capital not imposed. Capital valued by quasi-rent rather than capital services price.

TABLE 8.
IMPLICIT AGGREGATE OUTPUT AND INPUT PRICE INDICES

| Year | Output | Input |
|---|---|---|
| 1981 | 1.000 | 1.000 |
| 1982 | 1.042 | 1.003 |
| 1983 | 0.839 | 0.876 |
| 1984 | 0.886 | 0.940 |
| 1985 | 0.957 | 0.926 |
| 1986 | 1.201 | 1.030 |
| 1987 | 1.385 | 1.020 |
| 1988 | 0.662 | 1.016 |
| 1989 | 1.199 | 0.938 |

Note: Formed by Fisher's factor-reversal test.

TABLE 9.
TOTAL FACTOR PRODUCTIVITY GROWTH FOR ONLY GROUNDFISH TRAWL

| Year | Multifactor Productivity | Aggregate Output | Aggregate Input | Aggregate Biomass | Capacity Utilization |
|---|---|---|---|---|---|
| 1982 | -10.64 | 2.88 | 15.90 | -2.39 | < 1 |
| 1983 | -11.24 | -4.51 | 7.07 | -3.36 | < 1 |
| 1984 | 11.71 | -2.57 | -8.05 | -6.23 | < 1 |
| 1985 | 3.18 | 0.64 | -0.37 | -2.17 | > 1 |
| 1986 | 28.79 | -4.25 | -31.08 | -1.96 | < 1 |
| 1987 | -12.23 | -7.95 | 6.35 | -2.07 | > 1 |
| 1988 | 10.40 | 10.35 | 3.26 | -3.31 | < 1 |
| 1989 | 2.37 | 2.50 | 1.78 | -1.65 | > 1 |
| Mean: | 2.79 | -0.36 | -0.64 | -2.52 | |

Note: Differential power catchability correction (see text).
Pink shrimp and joint venture midwater trawl vessels excluded.
Correction for variation in capacity utilization (see text).
Tornqvist bilateral chain indices and percentage annual growth rates.

**SESSION 1 : FISHERIES COMMON POLICY**

**A : PLENARY SESSION**

The EEC-Common Fisheries Policy and the 1991-Report
P. Andersen ..... 15

The Fisheries Structural Policy on the Horizon of the Year "2000"
E. Mastracchio ..... 19

Définition et mise en œuvre de la Politique Commune des Pêches de la CEE : le point de vue d'un Etat membre
C. Bernet ..... 25

**B : INSTITUTIONS AND FISHERIES COMMON POLICY**

The Relationship between Fleet Capacity and Fishing Effort
G. Valatin ..... 29

The European Community Decision Making Process : Fisheries with Reference to the Role of the European Parliament
D.I.A. Steel ..... 37

The Common Fisheries Policy and the Role of Producer Organisations in South West England : Economic Considerations
J. Slaymaker, A. Hatcher and S. Cunningham ..... 45

**C : EVALUATING THE SOCIO-ECONOMIC IMPACT OF THE E.E.C. FISHERY POLICY**

Evaluating Socio-Economic Impact of EEC Fishery Policy Using a Social Accounting Matrices Approach
G. Cella, V. Placenti and M. Spagnolo ..... 53

**SESSION 2 : AQUACULTURE SECTORAL DYNAMICS**

**A : GENERAL SESSION**

A Comparative Study of the Development of Mussel Farming in Scotland and Ireland with Emphasis on the Development of Marketing
M. Gabbot, S.A. Shaw and J. Gibbs ..... 77

Economic Evaluation of the Red Sea Bream Ranching in Kagoshima, Japan
J.R. Ungson, H. Hirata and Y. Matsuda ..... 87

Adoption of Innovations in the Norwegian Aquaculture Industry - Perceived Attributes
K. Hansen ..... 97

Scandinavian Aquaculture in a Global Perspective. A Study Concerning Structural and Marketing aspects
R. Cedrins ..... 109

**B : PANEL SESSION - SALMON PRICE AND MARKET**

What is the "Right" Price of Norwegian Salmon?
R. Hannesson ..... 119

Why 1991 Alaskan Salmon Prices Crashed
M. Herrmann and J.A. Greenberg ..... 129

**SESSION 3 : FISHERIES MODELLING**

**A : MULTI-OBJECTIVES MODELLING**

Multi-Objective Programming : an Application to the Pacific Whiting (Merluccius productus) Fishery
R.R. Enriquíez and G. Sylvia ..... 145

A Multiple-Criterion Optimization Approach for the Management of a Multispecies Fishery with Ecological and Technological Interdependencies
J.C. Seijo, O. Defeo and A. de Alava ..... 161

The Role of Multiobjective Policy Models in Fisheries and Aquaculture Development
G. Sylvia ..... 171

Bioeconomic Multispecies Modelling of the Barents Sea Fisheries
A. Eide and O. Flaaten ..... 183

**B : FISHERMEN BEHAVIOUR**

A Bioeconomic Model for Fish Harvest Technology
D.B. Sampson ..... 197

Dynamics of Resource and Fishermen Behaviour in Coastal Invertebrate Fisheries
J.C. Seijo and O. Defeo ..... 209

**C : OTHERS**

Analysis of Some Management Options for a Small Pelagic Fishery in Central Philippines
J.E. Padilla and P. Copes ..... 223

The Usefulness of Bioeconomic Models under biological Uncertainty : a Case Study of the Australian Southern Shark Fishery
S. Pascoe, T. Battaglene and D. Campbell ..... 237

Simulation Model of Factory Trawler Operation
I. Arnarson and P. Jensson ..... 247

The Nordic Fisheries Management Model - Themodel and the data for the Icelandic version
A. Danielsson ..... 261

Sources of Variance in the Economic Performance of New England Otter Trawl Vessels
I.J. Anwar, P. Lallemand and J. M. Gates ..... 273

A General Bioeconomic Simulation Model ofthe catching Sector of a Multispecies Fishery
P. Rodgers ..... 283

BEAM 4 - A Bio-Economic Model for the Simulation of Space-Structured Multi-Species and Multi-fleet Fisheries
P. Sparre and R. Willmann ..... 293

Gérez Vos Pêcheries
C. de Verdelhan ..... 305

**SESSION 4 : AQUACULTURE ENTERPRISE MANAGEMENT**

**A : GENERAL SESSION**

Profitability of Catfish on a Representative Multiple Enterprise Farm in the Southeastern United States Under Conditions of Risk
R.S. Pomeroy, S.M. Carlier and C.E. Curtis ..... 315

The Management Schemes for Brackishwater Pond Production
Mudiantono ..... 331

Dynamic Cash Flow Models in Aquaculture: Amplifying the Scope of Managers
C.S. Wright ..... 343

**B : PANEL SESSION**

Elaboration d'un modèle bio-économique dynamique relatif à l'élevage de la palourde de l'Atlantique *(Spisula solidissima)*
M. Martin, J.R. Wilson, L. Adambounou and R. Bouchard ..... 355

A Model for the Optimal Management of Sea-Bass Aquaculture
G.F. Rizzo and M. Spagnolo ..... 367

Simulation of Aquaculture Production for Economical and Environmental Impact
M. Spratt ..... 401

**SESSION 5 : CONSUMPTION AND DEMAND**

**A : CONSUMPTION AND DEMAND**

Consumer Ability to Discern Seafood Quality : Results of Experimental Studies
J.G. Anderson, C.R. Wessels ..... 417

Conjoint Analysis of the Japanese Salmon Market
Y. Kusakabe and J.L. Anderson ..... 427

Seafood Consumption and Giffen Behavior
R.S. Johnston and D.M. Larson ..... 437

The Changes Affecting the Demand for Fish and Fishery Products in Poland
A. Gwiazda ..... 449

Testing the Consistency of Fish Consumption Data with Neo-Classical Demand Theory
M. Burton and T. Young ..... 457

**B : FOOD SAFETY**

The Northeast United States Market for Blue Mussels : Consumer Perceptions of Seafood Safety and the Demand for Mussels
P.M. Brooks and J.L. Anderson ..... 463

Seafood Safety Assurances : Implications for Seafood Marketing and International Trade
C.R. Wessels and J.G. Anderson ..... 475

**SESSION 6 : INTERNATIONAL EXCHANGES**

**A : INTERNATIONAL TRADE POLICY AND COMPETITION**

Development of the International Trade in Seafood Products in the Context of European Economic Integration
J.P. Boule and P. Guillotreau ..... 485

U.S. Demand for and Canadian Supply of Fish Products
R.L. Mazany, N. Roy and W.E. Schrank ..... 501

Price Fluctuation and Substitution in the Groundfish Market
T. Trondsen ..... 517

The Icelandic Cod Trade : An Econometrically Based Simulation Model
R. Arnason and T. Felixson ..... 531

An Approach to the Management of Market and Resource Uncertainties : The Globalisation of Trade Information
J.-F. Mittaine ..... 555

The Market Outlook for Shrimp
M.-C. Yang ..... 561

Changes in Poland's Foreign Trade Management and Impacts on the Foreign Trade of Fishery Products
H. Nakonieczna-Kiesiel and J. Zieziula ..... 573

Le commerce extérieur français des produits de la mer en 1991
J. Dari ..... 581

Monopsony, Trade Restrictions and International Markets for Intermediate Seafood Products : The U.S.-Canada Herring Dispute
A. Emami, L.E. Queirolo and R. Johnston ..... 589

Price Linkages between Japanese and United States Markets for Sablefish and Thornyheads
J.D. Hastie, D. Squires and J.A. Elston ..... 599

The Alaskan King Crab Industry - An Industry in Transition
J.A. Greenberg, S.C. Matulich and M. Herrmann ..... 609

Java Sea purse seiners : the impact of innovation on performance
J.K. McElroy and Wijoprono ..... 617

**SESSION 7 : FISHING ENTERPRISE MANAGEMENT**

**A : ACADEMIC**

Coastal State Fisheries Management : Fleet Development Versus Trade in Fisheries Services
S. Cunningham and D. Whitmarsh ..... 639

La théorie économique de l'investissement dans le rétablissement des ressources naturelles renouvelables, avec référence spéciale au cas de la pêche du pétoncle géant aux Iles-de-la-Madeleine, Québec (Canada)
J.R. Wilson, F. Mendez and M. Fréchette ..... 647

Fishermen's Time Discounting Rates and other Factors to be Considered in Planning the Rehabilitation of Depleted Fisheries
J.P. Hillis and B.J. Whelan ..... 657

Hysteresis et comportements adaptatifs des pêcheurs artisanaux
H. Rey ..... 671

Prediction of Financial Distress in the Norwegian Fish Processing Industry
B. Dreyer and T. Vassdal ..... 683

**B : FISHING ENTERPRISE MANGEMENT**

Unemployment Insurance and the Length of the Fishing Season
N. Roy, E. Tsoa, W.E. Schrank and L. Mazany ..... 693

Multiproduct Tuna Fisheries in the South WestPacific
H.F. Campbell, A. McIlgorm and R.B. Nicholl ..... 715

Portfolio Selection in Fishing Strategies in a Multispecies Trawl Fishery
S. Hanna ..... 727

Un essai d'identification des stratégies de pêches : le cas de la pêche artisanale dans le nord de la France
F. Lantz, M.-O. Allard and R. Junaueir-Lopez ..... 745

The effect of government subsidies on the formation of collusions in an oligopolistic fishery
P. Mickwitz and M. Hildén ..... 759

Productivity Measurement in Common Property Resource Industries : an Application to the Pacific Coast Trawl Fishery
D. Squires ..... 769

**SESSION 8 : FISHING REGULATORY TOOLS**

Fundamental Issues in the Design of ITQ Programs
L.G. Anderson ..... 787

Marketing Losses in Regulated Open Access Fisheries
J.E. Wilen and F.R. Homans ..... 795

The Role of Economics in the Development of Limited Entry Programs : Two Examples from Groundfish Fisheries in the Western United States
J.D. Hastie ..... 803

Exvessel Price Behavior in West Coast U.S. Groundfish : Implications for the Choice of Fishery Management Technique
S. Hanna ..... 813

Multiproduct Supply under Production Quota : an Application to Pacific Fisheries
D. Squires ..... 827

The potential Benefits of Individual Transferable Quotas and their Effects on Industry Structure
D. Squires ..... 839

Productivity and Efficiency of the Fishing Fleet : the Case of the Small Scale Fishing Enterprises in Boulogne
C. Ioannidis and F. Lantz ..... 851

Setting Total Allowable Catches based on Market Conditions : Economics of Atlantic Herring Roe Production
R. Nowak ..... 859

Fisheries Regulation and the Incentives to Overfish
R.L. Mazany, A.T. Charles and M.L. Cross ..... 873

Fixed or Variable Catch Quotas with Irreversible Investments
S.I. Steinshamm ..... 881

Renewable Resource Market Obeying Difference Equations : Stable Points, Stable Cycles, and Chaos
C.C. Duarte ..... 891

Individual Fishing Rights : Some Implications of Transferability
P. Copes ..... 907

Considerations for an Individual Transferable Quota Program for the South Atlantic Mackerel Fishery
K.F. Wellman, J.W. Milon and J. Gauvin ..... 917

From Open Access to Communal Property : the Case of the Fishing Community in Muxía.
A.G. Allut ..... 929

Impact of Product Mix on Optimal Fishing Quota
I. Arnarson and P. Jensson ..... 937

**SESSION 9 : DISTRIBUTION AND PROCESSING**

UK Fish Processing Industry Strategies: From the CFP Decade to the Single Market
J.A. Young and J.F. Muir ..... 955

Stratégies des industries de transformation et approvisionnement en produits halieutiques : le cas du Sénégal
M. Dème and M. Bakhayokho ..... 971

Stratégies technologiques dans les industries de transformation
L. Temri ..... 979

Consumption of Seafood, Poultry and Meat in Restaurants vs. Supermarkets
T. Naito, R.S. Johnston and A.L. Shriver ..... 989

Cross-Hedging Fishmeal with Soybean Meal Futures
T. Vukina and J.L. Anderson ..... 1001

Market Analysis Institutional Behaviour and Marketing of Fish in Portugal
S. Cruz ..... 1015

Monopolistic Aspects of Word Trade of Fishing Industries in Portugal
S. Cruz ..... 1029

**SESSION 10 : MARKET, PRICE AND PRODUCTION SYSTEMS**

**A : GENERAL SESSION**

Market Structure and Prices : the Marseille Fish Market
A. Kirman ..... 1051

Relative Price Variability in Fisheries some Policy Implications
C. Ioannidis ..... 1059

The Market Interaction of Wild Salmon Fisheries and Salmon Aquaculture
C.S. Wright and P. Copes ..... 1071

Determinants of Price in the Portland, Maine Fish Auction
N. Ty and J.M. Gates ..... 1093

The Price Equalization Fund of the Fisheries in Iceland A Descriptive Study
O.Ö. Klemensson ..... 1105

**B : MARKET ORGANIZATION AND FISHERIES STATISTICS IN JAPAN**

Fish Marketing System Developed in Japan and Price Maintenance Mechanism
K. Miki and T. Yamamoto ..... 1115

Fishery Cooperative Association in Japan and its Vital Role in Fish Marketing
N. Odaka and T. Yamamoto ..... 1125

Supply and Demand of Fish and Fisheries Products in Japan
G. Bourguignon ..... 1131

Dual Structure of Japanese Marine Fisheries and Role of Fisheries Statistics in Fisheries Administration
T. Yamamoto ..... 1143

**SESSION 11 : RESOURCES VALUE AND CONFLICTS**

**A : RESOURCE VALUATION AND CONFLICTS**

On Inferior Goods and Giffen Effects in Recreation Demand Analysis
D.M. Larson and R.S. Johnston ..... 1163

International Issues in Valuation of Commercial and Recreational Fisheries
R.S. Johnston and A. Emami ..... 1175

Production Domestique, Absence de Marchés et Marchés Manquants dans les Economies en Développement : Analyse d'Impact de Projet dans le Secteur des Pêches
P. Failler and J.R. Wilson ..... 1189

Commercial Fisheries and Sport Fishing: Conflict and Cooperation
T. Kusakawa ..... 1201

Subsistence Fisheries in Alaska : Conflicts Within a Multiple Use Resource
H.T. Geier, J.A. Greenberg and M. Herrmann ..... 1213

**B : INFORMATION**

Information Needs and the Management of Joint Commercial and Recreational Fisheries : the UK Fishery for Sea Bass (*DicentrarchusLabrax*)
S. Potten, M. Dunn and D. Whitmarsh ..... 1223

The New Institutional Economics (NIE) Applied to the Fisheries : the Role of Information in the (Continuing) Solution of Resource Problems
J.R. Wilson and R. Lent ..... 1233

Cooperative Fishing Arrangements between Coastal Countries and Distant Water Fleets
L.E. Queirolo and R.S. Johnston ..... 1249

La comptabilité des ressources naturelles: une application aux ressources salmonicoles
A. Webster ..... 1259

**SESSION 12 : FISHING AND DEVELOPMENT**

Quelle Place pour les Pêches Africaines dans le Cadre de la Nouvelle Donne Mondiale ?
S.C. Nana Sinkam ..... 1273

Problématiques du Développement des Pêches
J. Weber ..... 1293

La Pêcherie de Crabe des Neiges au Canada en tant que Système : Variables, Interactions et Incertitudes
J.C. Brêthes and R. Dufour ..... 1301

Development and Diversification : Sustainability Strategies for a Costa Rican Fishing Cooperative
A.T. Charles and A. Herrera ..... 1315

Structure, Constraints and Development Options of Fish Processing and Marketing in Namibia
R. Lasch ..... 1325

The Welfare Impact of Improved Boat Modernisation Schemes (IBMS) in Pemalang Regency, Central Java - Indonesia
I. Susilowati ..... 1337

# Fishing Regulatory Tools
# by
# J. Catanzano and J. G. Sutinen

Du fait de l'évolution du Droit de la Mer vers le milieu des années soixante-dix, le secteur de la pêche dans le monde a subi des changements majeurs. Depuis lors, pratiquement tous les Etats côtiers ont mis en œuvre différentes formes de gestion de leurs nouvelles zones économiques exclusives, recherchant dans une large part à éviter les effets négatifs du libre accès. Les programmes de gestion existant n'arrivent pas à produire, quels que soient les moyens choisis, de bonnes performances économiques. Cette limite est essentiellement due à l'incapacité de ces systèmes de gestion à résoudre le problème fondamental du libre accès. Les méthodes de régulation les plus communément employées (restrictions des engins de pêche, limitation des heures ou zones de pêche, quotas et capture totale autorisée) ne visent pas à contrôler l'accès aux ressources. Ainsi, aujourd'hui, la plupart des systèmes de gestion des pêcheries s'assimilent davantage à la forme d'un libre accès contrôlé, n'étant ni véritablement un libre accès non régulé ni un accès complètement contrôlé. Les progrès des programmes de gestion vers l'amélioration des performances économiques et le maintien dans le même temps de l'objectif biologique de conservation de la ressource, ont été lents.

Il y a dix ans, les pêcheries gérées par quotas individuels représentaient moins d'une douzaine de cas documentés dans la littérature alors qu'aujourd'hui les cas sont nombreux et en croissance rapide. Certains pays paraissent même évoluer vers la voie d'une régulation exclusivement orientée vers des systèmes d'appropriation, transférant quelque uns des droits et responsabilités de gestion directement aux utilisateurs de la ressource. D'une certaine façon, la boucle semble bouclée. Alors les gouvernements renoncent aux principes de micro-gestion et leur préfèrent des systèmes de gestion directe par les utilisateurs, assimilables à une forme moderne de système de tenure qui ne sont pas sans rappeler

The world has witnessed significant changes in its marine fisheries since the wave of extended fisheries jurisdiction of the mid-1970s. Since then nearly all coastal states have implemented some form of fishery management in their extended economic zones, motivated in large part to avoid the hazards of open access fishing. Existing management programs, however, generally fail to produce good economic performance from fisheries. This failure is largely due to the inability of these management programs to overcome the fundamental problem of open access. The most common management regulations (gear restrictions, time and area closures, and quotas on total catch) do not control access to fishery resources. Thus, most fisheries today take the form of regulated open access, being neither pure unregulated open access nor complete controlled access. Progress towards management programs which yield good economic performance and biological conservation in tandem has not been swift, though it is improving.

Ten years ago fisheries managed with individual quotas numbered less than a dozen documented cases, while today there are scores of individual quota programs and the number is growing rapidly. Some countries even appear to be moving in the direction of regulated sole ownership, transferring many of the rights and responsibilities of fishery management to the direct users of the resources. To some extent, management appears to be coming full circle. As government withdraws from the micro-management of fisheries and turns over management responsibility to users, there seems to be a trend towards the modern equivalent of marine tenure systems, so common in traditional coastal communities [1].

(1) This is not to say that it is appropriate to convert all fisheries to a modern form of marine tenure systems. Many near-shore coastal fisheries are competing with other uses of the ocean space and resource. The externalties are so numerous and complex that the traditional marine tenure system cannot be expected to properly resolve the allocation issues in this modern setting.

les anciens systèmes courants de gestion des pêcheries-côtières par les communautés traditionnelles [1].

Les économistes attribuent les problèmes du libre accès à l'absence de droits de propriété pour l'usage exclusif des ressources halieutiques. Les quotas individuels et les systèmes de limitation des entrées sont deux formes de gestion par allocation de droits souvent proposées pour résoudre le problème fondamental du libre accès. Plusieurs des papiers contenus dans cette session abordent les problèmes et conditions spécifiques associés à de tels programmes de gestion.

A l'heure actuelle, la demande pour des analyses bio-économiques plus pertinentes se traduit par un intérêt des chercheurs vers une meilleure prise en compte des aspects plus réalistes des systèmes pêche ainsi que des objectifs de gestion. C'est dans cet esprit que les points de référence classiques pour le biologiste ou l'économiste (par exemple MSY et MEY), ont été dépassés et enrichis au travers de modèles plus élaborés de gestion des pêches. En ce sens les analyses contenues ici tentent d'explorer des voies pour la prise en compte des objectifs d'efficience assignés au système de gestion et des objectifs de redistribution, la prise en compte des comportements des pêcheurs visant à contourner la réglementation, l'analyse comparée des coûts de chacune des propositions de gestion envisagée. Un grand nombre d'études témoignent du besoin d'améliorer la mise en œuvre des programmes de gestion par allocation de droits en tenant compte des conditions plus réalistes qui sont celles de la production, du marché, des conflits.

Les caractéristiques fondamentales du système pêche sont revues pour incorporer des relations plus complexes telles que celles exprimées en terme de chaos pour la dynamique des stocks, ou encore d'instabilité en référence aux systèmes économiques de taxes et décalages temporels dans les processus de régulation.

Une des formes les plus courantes d'allocation de droits dans les systèmes de gestion des pêches est représentée par les quotas individuels, forme dans laquelle il est attribué à chaque utilisateur un droit de capture pour une quantité de poisson donnée et pour une saison délimitée. Plusieurs papiers de cette session abordent les questions associées aux systèmes de gestion par quota individuel. Elles concernent notamment des considérations sur

(1) Il ne s'agit pas de dire ici qu'il est envisagé et envisageable de transformer toutes les pêcheries en système moderne de tenure. Certaines pêcheries très côtières sont en compétition avec d'autres usages de l'espace marin et des ressources. Les externalités sont si nombreuses et complexes que les systèmes traditionnels de tenure maritime ne peuvent pas suffire à résoudre les problèmes d'allocation dans le contexte moderne des économies et des sociétés.

Economists argue that the problems of open access are directly related to the lack of property rights to the exclusive use of fishery resources. Individual quotas and limited entry are two rights-based management measures often proposed to overcome this fundamental problem of open access. Many of the papers in this section address specific problems and conditions associated with such rights-based management programs.

The demand these days for more relevant bioeconomic analysis is reflected by researchers' interest in explicitly accounting for more realistic aspects of the fishery system and objectives of fishery management. In this respect, the classical biological and economic reference points (e.g., MSY, MEY) are being extended and enriched in more elaborate models of fishery management. For example, the analyses and discussions contained herein explore ways to take into account distributional, as well as efficiency objectives, and to account for fishermen's evasive behavior and the cost of managing a fishery. The need to improve the implementation of rights-based management programs under more realistic conditions of production, markets, and resource conflict, is shared by a number of the studies in this section. The fundamental characteristics of the fishery system are revised to incorporate more complex relationships, e.g., chaos in the stock dynamics, and instability produced by taxes and lags in the regulatory process.

One popular form of rights-based fishery management is individual quotas, where users are assigned the right to harvest a given quantity of fish in a season. Several papers in this section address issues associated with individual quota management. These issues include consideration of eligibility and transferability, the consequences of multiproduct firms, and the linkages with product markets, when evaluating the prospects of individual quota programs.

Anderson addresses a set of important issues involved in the practical implementation of individual quota programs: eligibility, duration, transferability, ownership caps, management units, monitoring and enforcement, and initial allocation. Copes examines the differential impacts of transferable and non-transferable fishing rights in the context of limited entry and individual quota programs. He argues that transferability leads to a "transitional gains trap" that limits improvements in fishermen's incomes. Wellman *et al.* explore many practical aspects of implementing an individual transferable quota program in a mixed recreational-commercial fishery. Their analysis, conducted in the context of the pelagic mackerel fishery off the southeast coast of the United States, addresses the unique problems of initial allocation and transferability inherent in this two sector, recreational and commercial, fishery.

l'éligibilité et la transférabilité associés à ces droits, les conséquences de ce type de gestion pour les unités de pêche non spécialisées et les liens avec les marchés des produits pour l'évaluation des perspectives des programmes de quotas individuels.

Anderson développe un ensemble de questions majeures relatives à la mise en œuvre de programmes de quotas individuels : éligibilité, durée, transférabilité, choix du propriétaire, unité de gestion, suivi et contrôle et enfin première allocation. Copes examine les différents impacts de droits de pêche transférables ou non transférables dans des cas de limitation des entrées et de quotas individuels. Il énonce que la tran§férabilité aboutit à ce qu'il appelle « le piège des gains transitoires » qui limite l'amélioration des revenus du pêcheur. Wellman *et al.* présentent plusieurs aspects pratiques de la mise en œuvre de quotas individuels transférables dans le cas d'une pêcherie mixte, faite d'activités récréatives et d'activités de pêche professionnelle. Leur analyse, développée à partir de l'exemple des pêches pélagiques de maquereaux de la côte sud-est des Etats-Unis, aborde le problème spécifique à ces pêcheries mixtes, à savoir la première allocation des droits puis la transférabilité de ceux-ci entre les deux secteurs, récréatif et professionnel en présence. Les pêcheries plurispécifiques présentent également pour l'aménageur et les chercheurs des problèmes et questions complexes dès lors qu'il s'agit de l'introduction de droits de propriété. Au travers de ses deux communications, Squires analyse quelques-unes de ces questions au regard des firmes non spécialisées. Dans la première il tente de caractériser formellement le comportement d'offreur pour une entreprise multi-produit avec ou sans système de régulation par quota et il présente ensuite une application empirique illustrée par le cas des pêcheries américaines de « sablefish ». Dans son second papier, Squires utilise la nouvelle technique du prix virtuel pour modéliser les effets d'un système de gestion par quota individuel pour une pêcherie composée de deux groupes d'unités de pêche multi-produit dissemblables par la taille des entreprises. Son modèle lui permet d'évaluer les gains potentiels de rente dans de telles pêcheries.

Hastie s'intéresse quant à lui au rôle joué par l'analyse économique dans la configuration de deux programmes de gestion par introduction de droits. Il discute tout d'abord du développement d'un plan de gestion pour un système de licence d'entrée dans les pêcheries de poissons démersaux de la côte ouest des Etats-Unis puis, d'un programme de quotas individuels transférables pour les pêcheries de « sablefish » d'Alaska et pêcheries de flétan des Etats-Unis. Hastie conclut de ces exemples que l'analyse économique joue un rôle limité et qu'à l'inverse les questions d'ordre politique ou social étaient

Multispecies fisheries present managers and researchers with a variety of complex problems and issues. Squires' two papers analyze some important aspects of multiproduct firms subject to individual quotas. In the first paper he formally characterizes the supply behavior for a multiproduct firm with and without a quota regulation and presents an empirical application to the United States sablefish fishery. In the second paper Squires employs the new analytical technique of virtual prices to model the effects of individual quotas for a fishery with two sizes of multiproduct fishing firms. His model allows him to evaluate the potential gains in resource rent in such a fishery.

The role economic analysis played in shaping two rights-based management programs is described by Hastie. He discusses the development of management plans for a license limited entry program in the groundfish fishery off the west coast and an individual transferable quota program for the Alaskan sablefish and halibut fisheries in the United States. Hastie concludes that economic analysis played a limited role and that political and social issues were more influential in the decision-making process which produced the final plans.

Rights-based management is commonly believed to allow fishermen more flexibility to take advantage of market opportunities. This and other connections between the market and management is emphasized in papers by Arnarson and Jensson, Wilen and Homans, Hanna and Nowak. All of these papers support the argument by Arnarson and Jensson, and Hanna that policy measures, such as quotas, cannot be properly set without considering the production attributes of catch and the associated interaction with the market. There is a natural feedback loop between harvesting and market prices that needs to be taken into account if managers are concerned with the economic performance of management programs.

Nowak explores the prospects of setting a total quota based on market conditions in the context of the Atlantic Canadian herring roe fishery, concluding that such approach would not work well if the sole objective were to maximize industry profits. Wilen and Homans argue that it is difficult to foresee the magnitude and kinds of revenue gains that might be induced by efficient management, and cite three cases where management programs produced market effects that significantly exceeded production efficiency gains.

The efficiency gains or losses in harvesting needs to be assessed when deciding among management alternatives. A method for measuring efficiency is explored by Lantz and Ioannidis in their study of a small-scale French fishing fleet.

davantage actives dans les modes de prise de décision qui produisaient le programme final.

On tend à associer communément aux systèmes de droit des qualités supérieures en terme de flexibilité offerte aux pêcheurs pour saisir au mieux les opportunités commerciales. Ce point ainsi que d'autres connections entre système de gestion et marchés sont considérés dans les textes d'Arnarson et Jensson, Wilen et Homans, Hanna et Nowak. Tous ces auteurs mettent en avant le fait que les mesures de politique de gestion telles que les quotas ne peuvent pas être instaurées convenablement sans considérer les effets sur la production et les interactions associées aux marchés. Il y a une boucle naturelle entre captures et prix qui doit être prise en compte si le gestionnaire de la pêcherie s'intéresse aux performances économiques du programme de gestion.

Nowak s'intéresse aux perspectives que présente un système de quota global basé sur les conditions de marché avec l'exemple des pêcheries canadiennes d'œufs de hareng de l'Atlantique, et conclu que de telles options de gestion ne pourraient fonctionner que si le seul objectif était de maximiser le profit des entreprises. Wilen et Homans quant à eux, aboutissent à la conclusion qu'il est difficile de prévoir l'ampleur et la nature des gains qui devraient résulter d'un système de gestion efficient et citent trois cas pour lesquels les systèmes de gestion ont produit des effets sur le marché qui ont largement dépassé les gains de productivité. L'efficience des gains ou pertes de capture doit être évaluée entre les différentes alternatives de gestion. A cet effet, Lantz et Ioannidis proposent une mesure possible d'efficience mise en œuvre à partir de données relatives aux flottilles françaises de pêche artisanale.

Les caractéristiques dépendant directement des dynamiques propres aux ressources peuvent avoir des implications significatives pour l'efficience et l'efficacité de la gestion. Sur ce point, Duarte explore les implications pour la gestion de dynamiques de population qui suivent des équations de séries temporelles discrètes. Certaines valeurs des paramètres font référence au chaos, et à d'autres obstacles à la gestion.

Steinshamm s'intéresse à la question de l'efficience comparée de quotas fixes ou variables dans certaines conditions avec ou sans investissements irréversibles. Il apparaît que sous certaines conditions, les systèmes de contrôle des inputs sont supérieurs aux systèmes de contrôle des outputs.

Cette question du choix entre une option de contrôle des inputs ou des outputs est également traitée par Mazany *et al.* qui comparent les performances économiques de chacune des méthodes. Les pêcheurs sont supposés

Characteristics of the underlying resource dynamics can have significant implications for the efficiency and effectiveness of management. Duarte explores the implications for management of a population dynamics following a discrete time difference equation. Certain parameter values give rise to chaos, and other troublesome management problems. Steinshamm explores the issue of whether fixed or variable quotas are more efficient under uncertainty, with and without irreversible investment. Under some conditions, fixed input controls are superior to fixed output controls.

The issue of input vs. output controls is also explored by Mazany *et al.* who examine the relative economic performance of each method. Fishermen are assumed to be willing to violate management regulations under certain conditions. This paper develops a framework for evaluating which form of controls is more efficient when enforcement of the regulations is both costly and imperfect.

Another form of rights-based management is where a fishery is operated under communal property. The paper by Allut reminds us that theoretical predictions of the so-called tragedy of the commons is not always born out. Where access to a fishery is limited to a given group of fishermen, social dynamics can result in self-regulation, requiring no state control of the fishery. This is illustrated by the example of a Mediterranean fishery in which both access and resource use is controlled by a local community of fishermen through a cooperative system of exploitation. Fishermen actively protect their resource from outside competitors with the use of force. This system was not effective until an equitable method for sharing the returns from the resource was implemented.

This set of research papers has some unique qualities. Ten years ago, conference papers on management would not have given the prominence to rights-based methods that the present set of papers do. These papers also exhibit a depth of analysis and treat a diverse set of critical issues underlying rights-based management that is novel. This novel emphasis on rights-based management and depth of analysis appears to us to be a reflection of the strong shift on the policy front towards the consideration of rights-based management measures.

violer la réglementation sous certaines conditions. Ce papier développe une méthode pour choisir parmi les formes de gestion la plus efficiente quand le contrôle de cette gestion est à la fois coûteux et imparfait.

Une pêcherie fonctionnant sous un régime de propriété commune correspond à une autre forme de droit dans les systèmes de gestion. Allut nous rappelle ainsi que les prévisions théoriques liées à la « tragédie des choses communes » ne sont toujours pas « born out ». Lorsque l'accès à une pêcherie est limité à un groupe donné de pêcheurs, les dynamiques sociales peuvent apparaître comme une autorégulation, ne nécessitant pas de contrôle de la pêcherie par l'Etat. Ceci est illustré par un exemple de pêcherie méditerranéenne dans laquelle à la fois l'accès et l'usage de la ressource sont contrôlés par la communauté locale de pêcheurs au travers d'un système d'exploitation coopératif. Les pêcheurs protègent leur ressource vis-à-vis des compétiteurs extérieurs par l'usage de la force. Ce système n'était pas effectif jusqu'au moment où une méthode de partage équitable des résultats a été mise en œuvre.

Les textes regroupés dans cette session présentent des qualités particulières. Il y a dix ans, les communications relatives à la gestion, ne témoignaient pas d'une aussi forte référence aux méthodes de gestion par allocation de droits comme c'est le cas dans cette session. Ces communications illustrent un approfondissement de l'analyse et un traitement nouveau des questions majeures liées à la gestion par allocation de droits. Cette nouvelle priorité donnée aux droits et l'élargissement des analyses nous paraissent refléter un fort changement sur le plan politique vers la prise en considération de mesures de gestion conçues en terme de droit.

# Fundamental Issues in the Design of ITQ Programs

**Lee G. Anderson** *

College of Marine Studies and The Department of Economics, University of Delaware, Newark, DE 19716-3501, USA

ABSTRACT

*Because of their potential to alleviate or reduce many of the problems associated with traditional management i.e., depressed resources, overexpanded fishing fleets, low fishermen incomes, interest group conflict, and the treadmill operation of management agencies as they try to keep with the system, ITQs have been implemented in, or are being considered for, many fisheries throughout the world. However, the actual benefits achieved from ITQ will depend upon how the specific program is adapted to the particular fishery.*

*The purpose of this paper will be to list the necessary components of an ITQ program and describe how they can be designed with reference to two different fisheries. The components described include : number and groupings of species and species aggregations, enforcement and monitoring procedures, initial allocation rules, transferability options, caps on ownership, other required management tools, etc.*

## 1. INTRODUCTION

ITQs are a regulation tool that can simultaneously address the necessary biological aspects of management and avoid some of the problems of traditional management techniques. They can provide operators with the flexibility to increase their profits by lowering their costs (by finding the most efficient way to harvest fish) and by increasing their revenues (by selling their products at those times and in those markets where prices are higher). This flexibility comes from the fact that fishery managers do not have to tell the harvester how to operate. The manager's job can also be easier because he or she does not have to worry about derby openings or about trying to figure out ways of keeping the catching power

* The material in this paper draws heavily on a report prepared under contract to National Oceanic and Atmospheric Administration, National Marine Fisheries Services, U.S.A. I am grateful for helpful comments from Wade Griffin, Daniel Huppert, Wally Milon, Jon Sutinen, and Rebecca Metzner. The views presented are my own and do not necessarily represent those of the above nor the National Marine Fisheries Service.

of a fishing fleet to a level that will not overfish the stock. By facing the allocation decision at the outset, the dual questions of how much to catch and who can catch it are separated. This separation leads to a system which can provide incentives matching the fishing power of the fleet to the productivity of the fish stocks.

This is not to say that ITQs do not have their problems. There are draw-backs, especially in certain types of fisheries. One special issue is that ITQs are a new and fundamentally different way to manage fisheries even though similar concepts are used in other types of resource management. The following sections describe issues which must be faced when designing ITQ programs. How they are faced will partially determine how many of the potential advantages of ITQs can actually be achieved and how potential problems can be addressed.

## 2. THE NATURE OF THE PROPERTY RIGHT

The basic differences between an ITQ program and traditional management tools are the "I" and the "T", the individual ownership and the transferability. Although the basics of the "I" and the "T" have been explained above, their true character is much more complex. The exact nature of the ownership right can have many facets, some quite subtle and others very overt. The nature of the right can be changed or limited to accomplish biological, managerial, or cultural objectives - any of which may be fully within the purview of overall fisheries management. However, it is important to compare what is being gained by meeting these other objectives to what is being lost by the diminished flexibility.

The basic issues concerning the nature of the property right are summarized below. The format will be to describe the issue and then to present a one or two sentence statement summarizing the various points of view. Finally suggested options to address the issues are provided. In some instances there may be legal considerations that will have to be addressed before using some options.

### *2.1 Eligibility To Own*

Should any legal entity be allowed to own ITQ or should ownership be limited to natural persons ? On the one hand, preventing corporations from participating may help maintain industry and community structure. At the same time, the limited flexibility may prohibit ITQ owners the opportunity to organize their activities to their best advantage and this may adversely affect the way the Nation's fish stocks are used to accomplish other management goals.

Options :

- Allow any legal entity the right to own ITQ shares.
- Allow only persons the right to own ITQ shares.
- Establish other restrictions on eligibility such as banning foreign ownership.

### *2.2 Duration Of Ownership Right*

In the U.S.A., should the ownership right be permanent, or should it be for some limited period ? According to current interpretations of the MFCMA, the ownership right at most can be guaranteed only as long as the management plan which implemented the ITQ program is in effect. By allowing the ownership right to be as permanent as current policy allows, the ITQ owner will have the securest possible planning horizon and will have better incentives to make efficient investments in harvesting and processing equipment and to develop market channels. On the other hand, there may be hesitations to make long term plans if the ITQ share may be given to someone else at a later date.

However, councils may wish to set limits on ownership rights to maintain some long term control over the fishery. By setting a term of X years, a council will have the opportunity to reassign rights if it feels current owners are not using them properly. However, doing so would require that the councils face the very difficult distributional task of reallocating the rights at regular intervals.

Options

- Ownership rights can be assigned for the duration of the ITQ program.
- Ownership rights can be assigned for fixed, perhaps renewable, terms.
- Ownership rights can be temporary initially, but after a trial period, made permanent.

*2.3 Transferability I*

A fundamental issue is whether ITQ rights should be transferable at all. Some would argue that an individual quota makes sense because it allows for better biological management, but that making the rights transferable is not appropriate because it is a permanent and free (given the current Magnuson Act) consignment of a public resource to a private individual. If, however, restrictions on transferability are permitted, they would constrain the flexibility of owners, which as described above is one of the potential advantages of ITQs. Additionally, with no transferability, a council must devise a way to reallocate the ITQs once an owner has died or retired from fishing. Without transferability, the allocation question must be faced over and over again.

Options

- ITQs can be fully transferable by sale, lease, gift, inheritance or through joint-harvesting arrangements.
- ITQs can be sold but the rights to catch fish in any one year cannot be leased.
- ITQs can be made non-transferable. The individual who receives the right is the only one that may harvest the fish.

*2.4 Transferability II*

Even if ITQs are to be transferable, limitations on the types of trades that are permitted may be justified in certain circumstances. The initial allocation will likely include individuals who differ by gear type, boat size, firm size, type of final product, home port, etc. Free transferability between all such individuals may result in changes in the industrial or cultural aspects of the fishery which the council may wish to prevent. Restrictions on transfers between specified groups may help prevent such changes. However, they will also limit the flexibility of ITQ owners and in the long term could become a stifling influence on the development and utilization of the fishery as a whole.

Options

- Place no restrictions on the transferability of ITQ between different groups of owners.
- Determine critical groupings of participants and prohibit or restrict purchases, leases, etc. between members of these groups.

*2.5 Ownership Caps and Restrictions*

There is often concern with the potential for creating "excessive shares" when implementing ITQ programs. Although there is no clear definition of what an excessive share is, it likely refers to market power for ex-vessel fish, final product, or even ITQ shares. It could also refer to the general historical, industrial, and cultural make-up of the fishery. Councils can take specific actions to address these issues or they may determine that other applicable laws are sufficient for doing so. For example, current anti-trust law addresses problems of excess market power in any industry including fisheries, and the council may conclude that this is adequate. On the other hand, councils may have an interest in directly addressing such issues in the construction of an ITQ program. If this is done, however, the difficulties of defining market power and of measuring the gains and losses of various actions, such that they can be approved as part of a management plan, should not be underestimated.

Options

- Place caps on the percentage of ITQs for a particular management plan or for a particular stock within a management plan that any one entity can own.
- Place other restrictions on how firms or individuals can combine to harvest the ITQ. For example, limit the percentage of total catch that can be landed by one boat or landed in one port.

## 3. MANAGEMENT UNITS

Defining the management unit or units is an important part of any fisheries regulation program. This is no less true with an ITQ program. A management unit in an ITQ program is the species, stock, or aggregation for which a TAC is specified and for which harvesting rights are distributed. In the Surf Clam and Ocean Quahog ITQ program, there are only two units : Surf Clams throughout their range and Quahogs throughout their range. At the other extreme, the proposed ITQ program for Alaskan Sablefish and Halibut has many management units. Each stock is broken down into several geographic areas.

Selecting and defining the management units for an ITQ program is a very important step. The success of the program can depend critically on how well it is done. There are two types of questions pertaining to the selection and definition of the management units that must be answered.

The first question is : How many species should be included in the program ? If different species are biologically or commercially related, there may be grounds for managing them jointly under the ITQ program. Some of the considerations that need to be addressed are : 1. Are the species caught as a by-catch or a directed catch with the same gear or by the same fleet ? 2. Are there ecological or spawning relationships between the species ?

Care must be taken when selecting the stocks. There are two types of errors that can be made. An error of exclusion occurs when a species that is closely related to those in the ITQ program is left out. This can make it difficult to appropriately manage the species that are in the program and/or the one that is left out. For example, if the catch of a species which is not covered in an ITQ program has a significant by-catch of a species which is included, it may be quite difficult to account for by-catch mortality.

On the other hand an error of inclusion occurs when a minor or unrelated species is included in the program. Determining and enforcing the TAC for such a species can involve more work and managerial repercussions on the major species than the gains from managing the minor stock are worth.

The second question is : How should each of the included species be classified ? There may be several stocks or geographically distinct units of the same species. If so it may be appropriate to have a separate TAC for each. At the other extreme, there may be certain groups which may be treated as aggregations for management purposes even though they are technically made up of separate species. Rockfish in Alaska is a good example. These aggregations can have a joint TAC.

Here again the decisions are critical. An error of conglomeration can occur if biologically distinct stocks are not separated. A single overall TAC on two separate stocks may put too much pressure on one stock if it is closer to port or has a higher catch per unit of effort. On the other hand, an error of specificity may occur if the different species are divided into too many stocks because the program can become unwieldy and difficult to manage.

There is definitely a trade-off in answering these two questions. The larger the number of stocks that are included in the program, the more inclusive the system will be and the lower will be the need for a separate management program to handle species and stocks not included. And, the more finely the quota share stocks are geographically defined, the easier it will be to focus management on more narrowly defined species or species groups if there are biological, technological, or distributional reasons for doing so. However, the larger the number of area divisions, the more complex and difficult it will be to manage the ITQ program. There will be more TACs to set, and the monitoring program will have be able to distinguish landings according to the stock from which they were harvested.

## 4. THE DETERMINATION OF THE TOTAL ALLOWABLE CATCH

Because the TAC is the main biological component of an ITQ program, it is essential that it is set with care. TACs are used in many other types of fisheries management programs, whether as actual binding limits or as implicit or explicit targets to be achieved using gear restrictions, season closures, etc. For the most part, the rules and procedures for developing TACs under other programs can apply under ITQ programs as well. The basic idea is to set a total fishing mortality level that is a balance between what can be taken this year and what should remain to grow and/or reproduce for future years. Application of this principle will vary according to the population dynamics and the current status of the stocks under consideration.

There are some facets of TAC determination under an ITQ program that merit special consideration. One very important issue is the definition of the harvest right especially when TACs will likely vary from year to year. The right to harvest cannot be defined in terms of a constant amount of fish each year. In the extreme case this would mean that the TAC, which by definition is the sum of the individual quotas of all participants, could never change. The right to harvest a particular stock must depend upon the current productivity of the stock. Therefore ITQ programs work better if the individual rights are defined in terms of a percentage of the TAC. As the TAC goes up or down according to biological conditions, the individual right to harvest in terms of actual catch will vary accordingly.

Another issue is how to set TACs in those fisheries which have not previously used them. In newly developing fisheries, the accumulated biological data may not be deemed sufficient. In other fisheries, current management may be based on the notion that biological issues can be addressed without using TACs. With New England scallops, for example, the assumption is that appropriately enforced meat count limits will be sufficient to protect the stock so TACs have not been used. They have not been used with shrimp either because shrimp are essentially an annual crop the size of which can vary depending upon factors other than the number of spawners, and so recruitment overfishing is unlikely.

If ITQs are to be used in these situations, the relevant question is : Are the gains from a reduced race for fish and increased flexibility of participants worth the effort and possible drawbacks of instituting TACs ? In developing fisheries, is the best information available sufficient to draw the balance between setting TACs too high and adversely affecting future catches and setting them too low so that current harvests are not unduly restricted ? With scallops, can TACs be set that achieve the biological objectives as efficiently as meat counts ? With shrimp can a TAC policy be established which can estimate, with in-season adjustments if appropriate, the amount of biomass available for harvest ?

There are two questions relating to TACs in shrimp and other short-lived species. Why set one ? How can one be set ? Shrimp is an annual crop, the size of which is not directly related to the harvesting pressure in previous years. A natural question, therefore, is why should there be a limit on harvest in any given year ? Limiting harvest in one year will reduce benefits that year but will not likely have a positive effect on catch next year. This is a valid point, but framing the question this way ignores many other important considerations. For instance, although total effort in the Gulf Shrimp fishery in the U.S. has been increasing steadily in the recent past, total catch has not increased proportionately. In fact, for the past few years, total catch has leveled off. There are indications that total effort could be substantially reduced without significantly affecting total annual catch.

Although increased effort has not increased catch, it has increased the difficulties of managing the fishery. For example, inshore closures are harder to enforce the more boats there are. In addition, the incidental harvest of turtles and finfish is likely to be proportional to total effort even if total shrimp harvest is not. Put simply, a reduction in total potential effort could reduce many of the fishery's other management problems.

But the issue is more involved than just inshore closures and by-catch. It is also important to look at the problem of waste from a broader perspective. On the one hand, having a system which may allow some shrimp to die unharvested undoubtedly involves a waste of fish. On the other hand, a system which can harvest the very last shrimp even in peak years will also have waste. When average years come, the fleet cannot be fully utilized and that is a waste of fishing capacity.

An advantage of an ITQ system is that it can address both types of waste. If individuals know that they have a right to a share of the available harvest, they will be motivated to build their harvesting capacity such that they can make the most of the good years, and at the same time not suffer large losses in medium or bad years. There will not be a race to catch fish, so ITQ owners can plan where, when, and how to take their share. Concurrently, by-catch problems can potentially be reduced because a smaller amount of effort applied at different times and in different locations will be used to take the allowable catch.

Another consideration pertaining to TAC setting is the relationship between TAC determination and the other components of the ITQ program. As discussed above, there are a wide range of issues to be considered in selecting the number and make-up of the management units, and one that deserves special mention is the basis for determining a TAC. Put simply, there needs to be sufficient theory and data to set a credible TAC for a certain species in a specified geographical area. If the problem is a lack of data, it can potentially be overcome. However, if the management unit is defined purely on political grounds, the problem of a credible TAC will remain. In summary, another drawback to expanding the number of management units is the increased data needs and work load of setting one more TAC.

The setting of TACs can also be related to certain enforcement problems. If it is likely that highgrading and by-catch discards will result in fishing mortality that is significantly different than landings, and if there are no other satisfactory ways of correcting for this, adjustments in TACs may be appropriate. For example, if participants can be expected to discard smaller less valuable fish of a particular species and if the smaller fish normally represent 10 % of the catch, the TAC can be reduced by 10 % of what it otherwise would have been.

## 5. MONITORING AND ENFORCEMENT

A fisheries management program is only as good as its monitoring and enforcement system. This is as true of ITQs as of other types of management. However, there will be some fundamental differences in the formulation and operation of a suitable monitoring and enforcement system for an ITQ program. ITQs are like any other TAC based program in that there must be a way to monitor total harvest and to ensure that it does not surpass the TAC. In addition, however, it is necessary to monitor the harvest of each participant and to ensure that it does not surpass his or her current individual quota level. With transferability, it is also necessary to keep track of the current amount of individual quota owned by each participant. While these extra burdens may seem formidable, it is necessary to evaluate an ITQ management and enforcement system relative to those of other types of management programs and relative to the potential management benefits of an ITQ program. Will overall monitoring and enforcement costs be higher or lower ? Even if the costs are higher, are the accomplishments of ITQ management worth it ?

The successful operation of an ITQ program requires that the monitoring system be seen as being capable of detecting abuse. Participants must be confident that others can not beat the system and thus diminish the value of their rights. In addition the participants must also know that the system will detect any misconduct on their own part so incentives to cheat will be small. However, this does not necessarily mean that every fish brought to the dock and every landings report filed must be personally inspected by an enforcement officer.

In-person inspections will still be important aspects of an ITQ monitoring system, but their ultimate success will require a computerized system of electronic reporting and data management. In addition, there must be at least two sources of information for any transaction. For example, both the harvester and the first fish receiver must fill out independent landing forms that can subsequently be double checked against each other. Similarly a transfer of individual quota from one person to another must be verified in writing by both parties. The computer system should have a series of tests that can be run frequently to verify the accuracy and consistency of reported landings and trades.

The work of monitoring agents will change under an ITQ program. The emphasis will shift from checking the day to day operations of the fleet to monitoring catch levels. It is unclear whether the actual amount of monitoring activity or its cost will increase or decrease with an ITQ program. Depending upon the circumstances, it is likely that at-sea monitoring, which can be very expensive, can be significantly reduced. On the other hand the amount of book-keeping type activities will likely be increased. Concurrently, because participants have a long term interest in protecting their harvest rights, they will be more inclined to adhere to the rules and to assist agents in detecting abuse from others.

Permits for both harvesters and processors will likely be a crucial part of an ITQ monitoring system. These permits should be available to any interested party at a nominal fee. A fisherman would be required to obtain a harvesters permit in order to own or lease ITQs. Any harvesting activity would be recorded against the harvesting permit number. Processors would be required to obtain a fish receivers permit in order to buy fish landed under the ITQ program. All purchasing and processing activity would be recorded against the fish receivers permit number. The idea behind a permit program for processors is two-fold. First, it provides for the double entry system that is necessary to establish proper supervision. Second, it provides for a broader based enforcement program. If processors have to show that fish in their possession was legally harvested, they will be very careful from whom they buy. If they will not buy illegal fish, there will less incentive for ITQ owners and non-owners alike to bring in non-quota fish.

Penalties for non-compliance should be firmly established, rigorously enforced and severe enough to encourage compliance. For intentional and rampant cheating, there should be provision to revoke harvesting or fish receiving permits and even to confiscate the basic ITQ harvesting right.

## 6. OTHER REGULATIONS

The heart of an ITQ program is the TAC. If properly enforced, it will ideally address all conservation issues. However, it is not hard to conceive of instances where conservation issues are not satisfactorily addressed in a basic ITQ program. The following are illustrations.

- A stock may be especially vulnerable to exploitation in a particular location or during a particular season. If this is the case, there may still be incentives for ITQ owners to gear up to make their catches at these times or locations so as to lower their costs. There will still be a race for catch, although it will be limited to fewer participants.
- If the TAC for one species is taken in a particular area, during a particular season, or with a certain type of gear or fishing method, the by-catch or discard mortality of other TAC species may higher than would otherwise be the case.
- Individuals in a particular stock may exhibit high growth rates over a season such that the biomass and value increases if a fish is taken later in the season.
- Fishing in nursery grounds or during spawning periods may have larger effects on future stock sizes than taking equivalent catches at other times or places.

If these or other situations occur, the actions of individuals trying to maximize their profits from their ITQs may result in harvesting patterns which do not optimally utilize the long term productive capacity of the stocks. In short, the TACs will not always address all of the biological concerns, and in such instances, it may be worthwhile to consider supplemental regulations.

The exact additional measures that will be worthwhile to institute, if any, will depend upon the particular circumstances of the fishery. A suggested approach for addressing these problems is :

i) Describe exactly the conservation problem that will not be addressed by a basic ITQ program.

ii) List possible ways in which the ITQ program can be modified so as to solve the problem.

iii) List possible supplemental regulations that will address the problems.

iv) Determine which of the potential solutions derived in Items ii and iii best addresses the problem and specify a modified ITQ program which incorporates these additional rules or procedures.

v) Compare the basic ITQ program with the modified ITQ program to determine which one most adequately addresses the management objectives. If the modified one is judged superior it should be adopted ; if not, the basic program should be used (assuming that an ITQ program is to be used). The basic issue is to make sure that the modifications do not introduce problems worse than those they solve.

Consider the case where there are nursery grounds or spawning periods where harvests can have significant long term effects. If the quality of the flesh or the product recovery rate falls during spawning, this may not be a problem because ITQ owners may not want to use their ITQs on lower valued fish. However, if costs are reduced by fishing spawning aggregations or if the roe is commercially valuable, there may be incentives to harvest spawning fish rather than at other times of the year which may create a potential problem for optimal utilization of the long term productivity of the stock.

The problem could be addressed within an ITQ program by adjusting the TAC level. Or it may be possible to assign coefficients that would transfer catches at different times of the year into equivalent terms with respect to future stock sizes. For example, each ton of fish harvested during the spawning period could count as 1.5 tons of fish harvested during other periods of the year. This would allow individuals the flexibility to operate when they wanted, but it would force

them to consider the long range effect of their decisions. This adjustment would increase management costs. Research would be necessary to calculate the appropriate coefficients, and enforcement would become more complex and perhaps more expensive.

The problem could also be addressed by adding a supplementary regulation that fishing not be allowed in spawning areas or during spawning periods. This would likely be easier to enforce but its inherent lack of flexibility may reduce the potential gains to individual operators that ITQs can provide. It is important to make sure that the gains that are provided in an ITQ program are not taken back by supplemental restrictions unless it can clearly be shown that the overall gains are greater than the costs.

The ultimate questions are which of the two modifications best addresses the problem and if it is adopted, does it provide an overall improvement in the system as a whole ? The answer will depend upon the exact biological, economic, and institutional characteristics of the fishery involved.

## 7. INITIAL ALLOCATION

The initial allocation of quota shares to individuals is obviously very important. It will, for the most part, determine who gets the gains from an ITQ program. It will determine who will be the initial participants in the fishery. How future participants will be determined depends upon the rules for transferability and the duration of the ownership rights. The importance of this decision notwithstanding, for the most part the initial allocation issue is independent of other components of an ITQ program. It is, after all, a once-and-for-all-step. Given flexible transferability rules and non-expiring ownership rights, allocation decisions only have to be made once. In order to maintain a balanced focus when considering ITQs, the independence of the initial allocation question from the other five fundamental issues (sections 2-6) should be high-lighted. Otherwise, it is possible that the distributional issues will unnecessarily cloud or over-shadow the discussions of other important, but basically independent issues.

There are literally an infinite number of initial allocation options. An option that is suitable for a particular fishery can be developed by answering the following questions.

i) Will the rights be sold or given away ? If the rights are to be sold, will it be by an auction, by sealed bids, or by some other means, and will existing participants be given a preference ?

ii) If the rights are to be given away, how will the pool of recipients be selected ?

iii) Once the pool of recipients has been selected, on what basis will the quota shares be distributed among them ?

iv) Will the quota shares be based solely on the definition of quota share stocks, or will they be further sub-divided by vessel category, gear type, or some other classification ?

# Marketing Losses in Regulated Open Access Fisheries

**James E. Wilen[a] and Frances R. Homans[b]**

[a] Department of Agricultural Economics, University of California, Davis, CA 95616 U.S.A.

[b] Department of Agricultural and Applied Economics, University of Minnesota, St-Paul, MN 55108 U.S.A.

ABSTRACT

*Much of the focus of fisheries economists' analysis of common property inefficiencies has been on the production cost side of the ledger. For example, the fundamental problem has often been described as " too many boats chasing too few fish." As a result of this view of the problem, policy recommendations have evolved through gear restrictions, limited entry, and buy-back programs, all aimed at harvesting efficiency and inputs. Ignored in all of this is the impact of common property incentives on the market or revenue side of the ledger. Casual observation suggests that there are widespread losses of revenues associated with common property exploitation that may even swamp the cost impacts. For example, the "race for fish" typical in many regulated open access fisheries often results in poor quality raw products (poor handling, lack of refrigeration, small sizes, no sorting) as well as poor quality wholesale products due to storage and freezing, etc.*

*This paper develops a model of marketing losses due to common property. We then conclude with the examination of the marketing and revenue impacts of recent introduction of ITQ's in the New Zealand groundfish fishery, the Australian Bluefin Tuna fishery, and the British Columbia halibut fishery. These cases verify one of the main hypotheses ; namely, that the gains from revenue improvements associated with higher quality products can be significant and may even swamp the production efficiency gains associated with moving away from open access and common property.*

## 1. INTRODUCTION

The literature in fisheries economics is dominated by a simple theme, namely that open access resource use dissipates the rent potential of fisheries. This theme has roots in the original paper by H. S. Gordon (1954) who analyzed the tendency for additional effort to enter beyond the point where marginal benefits equal marginal costs. A large amount of analysis has been devoted to comparisons of open access systems and various forms of regulated systems designed to correct the common property incentives.

This simple paradigm has been important in several respects to policy making in fisheries. First, by bringing attention to the rent losses inherent in open access resource use, it has resulted in important changes in the goals of regulation, away from reliance on steady-state biomass concepts and towards a focus encompassing economic efficiency and other social objectives. Second, it has fostered a broader set of policy options for consideration, including landings taxes, limited entry schemes, and recent Individual Transferable Quota (ITQ) systems in fisheries.

Although the simplicity of the basic open access paradigm has been mostly a virtue, economists have not paid enough attention to the complexity of real world rent dissipation processes and the implications for policy design. For example, the first limited entry programs were basically guided by a characterization of the rent dissipation problem as "too many boats chasing too few fish." As a result of this simple view, early programs which limited **boats** were quickly found to be ineffective as fishermen increased vessel capacity by altering other inputs. Regulators have responded haphazardly with restrictions on other dimensions of effort (such as length, tonnage, gear type) but without much guidance by economists about the nature of the choice process that fishermen use in selecting these inputs in an open access setting. An obviously important (but not well understood) variable input choice in fishing is **time** , both total fishing time and the split between fishing and searching/traveling time. Most regulatory programs regulate effective fishing time by using season length to reduce the actual impact of fleet capacity on catch. In many important fisheries, the impact of this has been a steady compression of fishing seasons into shorter and shorter periods.

The focus of this paper is on a neglected component of the rent dissipation process, namely the marketing losses associated with open access or regulated open access. Virtually all of the attention devoted by economists to the rent dissipation problem to date has been concerned with production inefficiencies. That is, nearly all analysis assumes that the major effects of open access behavior manifest themselves in inefficient production input choices, specifically, too many boats chasing too few fish, and/or inefficient input combinations in catching technology. This simplistic focus on the cost side of the profit equation runs a danger of leading to more ineffective policy recommendations and miscalculations about how the most significant gains from regulation might be achieved. Marketing losses occur in open access or regulated open access fisheries for several reasons. Foremost among these is poor quality raw product associated with the race to catch fish (gear damaged fish, undersized fish, lack of on board handling). Additional factors include reduced quality wholesale product associated with capacity bottlenecks, freezing deterioration, and inability to market when fewer substitutes are available. All of these translate into lower ex-vessel prices, which in turn affect the process of rent dissipation.

This paper presents a simple model which describes some of the components and consequences of marketing losses due to open access. In the next section, we present a model of a regulated open access fishery which reduces the comparison between an optimized fishery and the open access fishery to a few simple parameters. Then, in the following section, we discuss the implications of marketing losses in terms of the model's parameters and with three real world case studies. The final section summarizes.

## 2. MODEL OF A REGULATED FISHERY

The world has changed considerably since H. S. Gordon's seminal paper which described the process of rent dissipation in a purely open access fishery. The major changes have occurred as a result of the extension of jurisdiction in 1978 by coastal nations after the Law of the Sea negotiations. Since the extension of jurisdiction in 1978, virtually all coastal nations have had the ability, if not the resolve, to avoid the waste inherent in open access. As it has turned out, the evolution towards rationalized systems has been slow. Most fisheries today are neither open access nor anything approaching the sole owner ideal, but rather a hybridized system best called **regulated restricted** (or open) **access**. By this we mean that most fisheries retain vestiges of old biologically-determined effort restrictions within limited entry systems or in systems still open to everyone.

The most commonly observed regulatory instruments are gear restrictions such as net mesh regulations and season closures. Season closures are particularly important because they are in many fisheries the principle means of ensuring that targeted catches are not exceeded. They operate very simply : when potential effort is drawn into a fishery in response to profitability, its use is curtailed by restricting the season length over which the fleet can operate. Thus if effort increases ten percent in response to fishing profitability, we would expect the season length to decrease by a corresponding amount to hold catch constant. In a regulated open access or restricted access fishery, effort restrictions are essentially endogenous and are promulgated to ensure that a targeted catch is achieved.

These ideas can be formalized as follows. Suppose that we have a fishery whose pre-season exploitable biomass is estimated to be $X_0$. We assume for simplicity that natural mortality is insignificant and that there is no stock growth within the season so that the stock declines by the harvest h(t), where the harvest production function is $h(t) = qEX(t)$.[1] In this formulation, E is the effort level which is assumed to be constant and committed at the beginning of the season and q is a catchability coefficient. Costs consist of two components related to E, the first a cost c per unit effort per unit time and the second a cost v per unit effort. Consider first the benchmark case of a profit-maximizing industry facing a fixed price P that chooses E to maximize profit :

$$\max_E \Pi = \int_0^T [Ph(t) - cE]\,dt - vE \tag{1}$$

$$\text{subject to} \quad \dot{X}(t) = -qEX(t)$$

$$X(0) = X_0 .$$

For simplicity we ignore the discount rate. After solving the state equation and substituting, the objective function can be integrated directly to obtain

$$\max_E \Pi = PX_0[1 - e^{-qET}] - cET - vE \tag{2}$$

Under the assumption that the industry takes the season length T as given, the optimal level of E satisfies

$$E^* = \frac{1}{qT} \ln \left[ \frac{PqX_0 T}{cT + v} \right] . \tag{3}$$

To incorporate a model of the regulatory system, assume that regulators have a targeted end-of-season stock level that must be left after the fishery is completed. If this is denoted $X_T$, then the total allowable catch Q is simply the difference between the exogenous beginning stock and the targeted end of season stock[2]. Given that the state equation for the biomass is as in (1) above, the season length that ensures that the targeted stock will be achieved (with a beginning stock $X_0$ and effort level E) is given by

$$T^* = \frac{1}{qE} \ln \left[ \frac{X_0}{X_T} \right] . \tag{4}$$

Equations (3) and (4) together yield a description of a regulated fishery with (arbitrary) end of season stock level $X_T$, assuming that the industry chooses the restricted maximum profit level of E [3]. Solving these in terms of the model parameters yields

$$E^* = \frac{PqX_T - c}{qv} \ln \left[ \frac{X_0}{X_T} \right] \tag{5}$$

as the solution for the optimal level of E, and

1. This is a standard Beverton-Holt assumption which we adopt for simplicity. We are most interested in characterizing the within-season behavior of the industry and regulators in a simple fashion rather than between-season dynamics. This leads quite naturally to a structure where the biomass simply declines with cumulative fishing effort.
2. This is a simple way to capture the regulatory philosophy followed in many fisheries. It also appears objectionable to economists worried about efficiency and optimization. We should emphasize that we are modeling what regulators appear to do, rather than what they might do if they were trying to optimize.
3. Note that we have characterized all of the regulatory options that a management agency might use in a single control, the season length. In practice, regulators use other instruments but the intent is generally the same, namely to reduce the effectiveness of effort operating over the fish stock. Note also that (3) and(4) are structural decision equations. The industry is assumed to take season length as given and then maximize profits by selecting effort whereas the regulators take effort as given and choose season length according to the targeted catch.

$$T^* = \frac{v}{PqX_T - c} \tag{6}$$

as the solution for the optimal regulated season length [4]. These can be inserted into the profit function (2) to yield the maximized profits expressed as a function of the parameters, [5]

$$\Pi^* = PX_0 - PX_T\left(1 + \ln\left[\frac{X_0}{X_T}\right]\right) \tag{7}$$

Now consider the counterpart to the above regulated profit maximizing system, namely a **regulated open access** system. In this case, we assume that effort will enter until profits are driven to zero, or where

$$\Pi_0 = P_0 X_0[1 - e^{-qE_0T}] - cE_0 T - vE_0 = 0\,. \tag{8}$$

Note that we assume the price under open access is $P_0$, which may be different from the P achievable under optimized conditions. In this case we also assume that the regulators choose a season length that ensures the targeted terminal stock is achieved, or

$$T_0 = \frac{1}{qE}\ln\left[\frac{X_0}{X_T}\right]. \tag{9}$$

In this scenario, the rent dissipating effort level E can be determined to be

$$E_0 = \frac{P_0}{v}(X_0 - X_T) - \frac{c}{qv}\ln\left[\frac{X_0}{X_T}\right] \tag{10}$$

and the corresponding season length will be

$$T_0 = \frac{v \ln (X_0/X_T)}{P_0 q(X_0 - X_T) - c \ln (X_0/X_T)}\,. \tag{11}$$

Profits in this system are zero since rents are dissipated. It is easily seen that the effort level in the optimized system is lower than that in the open access system, as would be expected [6]. Since the product of the effort level and season length must be the same in both systems (see (4) and (9)), the season length in the open access system will be compressed, in order to ensure that the targeted catch is not exceeded with the higher level of effort.

## 3. MARKETING LOSSES AND RENT DISSIPATION

The incorporation of marketing losses associated with common property behavior has several impacts on the system modeled above. First note that marketing losses actually mitigate some of the normal effects of common property

4. The end of season stock level is left arbitrary. Once the initial stock is known, selecting the terminal stock is equivalent to selecting a catch target. Note also that we could in principle introduce more complicated optimization (such as between-season dynamics) by choosing the terminal stock as part of some dynamic plan, i.e. the terminal stock could also be the optimal terminal stock.
5. Note that this is a function of prices, the initial stock, and the regulator-chosen terminal stock. Costs are embedded in this equation since variable input costs are essentially determined by the regulatory choice of the terminal stock.
6. This condition is met whenever optimized profits are positive, which is always the case as long as the allowable catch is positive.

incentives because lower prices cause less effort to enter than would be the case otherwise. This allows a relatively longer season, although not as long as would be the case under an optimized system. In Figure 1 we show the combinations of effort and season length that achieve a fixed target catch under various scenarios. This relationship is depicted as a rectangular hyperbola, since $ET=(1/q)\ln(X_0/X_T)$ is assumed fixed by regulators under all scenarios. Under the optimized system at A, rents are maximized with low effort spread over a long season, with prices P. If there were no marketing losses, this same price would induce entry to point B, necessitating a very short season to ensure the targeted catch. With marketing losses reducing price to $P_0$, however, entry proceeds only to C, where a relatively longer season may be allowed.

A second implication of significant marketing losses is that the potential rent gains to be achieved under more efficient regulatory regimes will be underestimated unless the market losses are satisfactorily accounted for. From equation (7), we can calculate the total rents foregone under rent dissipation. Using (5) and (10) to calculate the excess costs $v(E_0-E^*)$, equation (12) shows that true rent losses can be partitioned into

$$\Pi^* = (P - P_0)(X_0 - X_T) + v(E_0 - E^*)\,. \tag{12}$$

Note that the first term is the revenue loss associated with poorer quality raw product and the second term is the excess costs generated with excessive effort. As $P_0$ and P diverge, $E_0$ approaches $E^*$ and the fraction of losses associated with marketing costs rises. Similarly, as $P_0$ approaches P, rent losses are dominated by production inefficiencies associated with excess effort. In evaluating regulatory changes such as limited entry/buyback and ITQ systems, it has been common practice to focus exclusively on production/capital cost savings associated with more efficient input use [7]. Equation (12) suggests two important problems with this procedure. First, by not considering potential marketing gains, the first term will be ignored. Second, by determining optimized effort under the assumption that common property marketing conditions will prevail, the level of the optimal effort $E^*$ in the second term will be underestimated [8]. Since this inflates the production cost saving estimates, these errors will be partially off-setting but the overall effect is still an underestimate of true potential rent gains. Using (5) to calculate $E^*$ with the underestimated common property price $P_0$, it can be shown that true potential rents will be underestimated by :

$$\begin{aligned}\Pi^* - \tilde{\Pi} &= (P - P_0)(X_0 - X_T) + v(E_0 - E^*(P)) - v(E_0 - E^*(P_0)) \\ &= (P - P_0)(X_0 - X_T) - (P - P_0)\,X_T \ln\left[\frac{X_0}{X_T}\right].\end{aligned} \tag{13}$$

As discussed above, this underestimate consists of the ignored marketing gains (the first term) offset partially by the second term representing overestimated production cost savings. An important empirical question which this discussion raises is : how large are the marketing losses associated with rent dissipation ? A rough idea of potential magnitudes can be inferred from three recent adoptions of ITQ systems in the Pacific Halibut fishery, the Southern Bluefin Tuna fishery, and the near-shore New Zealand groundfish fishery. The halibut fishery is a classic example of a fishery fitting the characteristics modeled above. As figure 2 shows, season length in the regulatory area 2A has been used to mitigate the potential impact of effort on the stock, with increased effort matched by decreased seasons. This fishery has pushed this scenario to extremes during recent periods, with seasons lasting for only four or five days of frenzied activity.

During the 1991 season, Canadian fishermen decided to conduct their portion of the fishery under a vessel quota system rather than the usual "fishing derby." The U.S. fishery was conducted in the normal fashion and there were reports that over fifty percent of the catch was landed without ever having been iced and about a third of the fish were not even gutted during the biggest one day opening in the first week of May. The British Columbians, in contrast, mostly chose to hold their quotas over to use after the May opening in the U.S. and before the final closing date of November. As a result significantly higher prices were obtained by Canadians. Fishermen's News (June 1991) reported that ex-vessel prices received during the later part of May by B.C. fishermen averaged $1.10 higher than those received by U.S. counterparts

7. Examples of attempts to compute rent gains from ITQ's include Dupont (1990), Geen and Nayar (1988), and Squires(1990).
8. This effort level is another point on Figure 1, say point D. This is the effort/season length combination associated with profit maximizing choice of effort at common property prices. Since by equation (5) the optimal effort is proportional to prices, this point lies to the right of point A. This in turn suggests that computing cost savings between points C and D will overstate them.

(who received about $1.70). This suggests a price "penalty" due to common property of about forty percent of potential. Similar results have emerged in the Australian Southern Bluefin Tuna fishery which converted to an ITQ system in 1984. Geen and Nayar (1988) report results of some simulations which attribute production cost savings of 25-30 % of the steady state common property fishery costs. More important, however, are the impacts on the revenue side. Significant shifts in fleet effort occurred towards regions where the average size of fish caught was larger due to the incentives to maximize revenues. In only three years of operation, the number of large fish (greater than 15 kg.) increased from 13 to 35 percent of catch This was induced by new marketing opportunities presented by the ITQ system, particularly the ability to serve the lucrative Japanese sashimi market. Significantly, revenues rose from 988 to 2000 dollars per tonne between 1984 and 1987, (in constant dollars) as a result of higher product quality and better marketing opportunities. In the New Zealand fisheries the evidence is even more startling. Early reports are that revenues **tripled** in some groundfish fisheries after the introduction of the ITQ system. This was made possible by a major shift in products marketed, away from mixed batches of small, trawl marked fish caught in compressed seasons, towards long-line caught fish, selected for size and market characteristics and spread over the whole year. Interestingly, this switch to a **costlier** technology was induced by the prospect of the marketing gains made possible by the regulatory change. Thus, in contrast to what most economists would have expected, in this case unit costs actually rose after adoption of a more efficient regulatory scheme but revenue increased more than compensated to increase profits. Needless to say, an *ex ante* analysis which attempted to predict rent gains in this fishery by examining production cost savings would have not only missed the most significant component of the rent gains, but also would have likely been carried out under the assumption that trawl technology would have continued to be in use.

## 4. SUMMARY

This paper discusses the implications of a source of rent losses not normally considered by fisheries economists ; namely losses associated with the marketing or revenue side of the profit equation. A model is developed which captures some important features of regulated restricted and open access fisheries. The model is then used to explore the implications of marketing losses. It is shown that market effects actually may mitigate the tendency towards excessive effort. However, if there are significant marketing losses, they must be accounted for when predicting or evaluating the potential of policy changes. In fisheries where our only experience is with traditional regulation regimes, it may be difficult to foresee the magnitude and kinds of revenue effects that might be induced by more efficient management. In three examples discussed here, the impacts appear to be very significant and potentially high enough to swamp any production cost savings.

ABSTRACT

*Fisheries occurring within the Exclusive Economic Zone of the western coasts of the United States have undergone tremendous changes since the implementation of the Magnuson Fishery Conservation and Management Act in 1977. Increases in fleet harvesting capacity have contributed to a growing list of problems facing fisheries managers, including reductions in the net fishery value, gear conflicts and an increasing number of contentious proposals for preferential allocation of the fish resource among various domestic user groups. In many instances, increased capacity has lead to substantial reductions in season length. These shorter seasons not only frustrate industry participants, they often create nightmares for managers, who must guard against excessive removals from the fishery, while at the same time achieving economic and social objectives.*

*Both the Pacific and North Pacific Fishery Management Councils have devoted considerable attention during recent years to proposals which would limit access to all or some of the groundfish fisheries within their jurisdictions. This paper reviews the development of two differing approaches to effort control : a vessel license form of limited entry, recently approved by the Pacific Council for their entire groundfish fishery, and ITQ proposals pending before the North Pacific Council for both sablefish (Anoplopoma fimbria) and halibut (Hippoglossus stenolepis). The paper reviews the limited role which economic analysis played in shaping the final proposals considered by each of the Councils. The availability of economic information for these analyses is discussed along with political and social issues which were influential in the decision-making process. Finally, the anticipated economic efficiency implications of these programs are assessed.*

## 1. INTRODUCTION

The objective of this paper is to describe the development of two very different proposals for limiting entry to U.S. groundfish fisheries, and assess the importance of economic analysis in their evolution. One of these programs would

limit entry to most of the groundfish fishery that occurs off the west coast of the U.S. (Washington, Oregon, California) through the issuance of a limited numbers of licenses. This fishery falls under the policy sphere of the Pacific Fishery Management Council (PFMC). The other effort, which evolved from two parallel proposals, would limit entry to sablefish and halibut fisheries off Alaska, through the issuance of individual transferable quotas (ITQs) for these species. This fishery falls under the policy sphere of the North Pacific fishery Mangement Council (NPFMC).

## 2. RECENT HISTORY OF GROUNDFISH FISHERIES OF THE WESTERN UNITED STATES

These proposals for limiting entry have not emerged from a vacuum. Both fisheries are subject to numerous management and economic problems. In order to place the emergence of the limited entry discussion in proper perspective, I will briefly review the recent history of these fisheries. At the foundation of the current fisheries management superstructure in the U.S. is the Magnuson Fisheries Conservation and Management Act of 1976 (MFCMA). This legislation not only created the regional fishery management councils, who establish much of the policy for managing the fisheries, it also established an exclusive economic zone, between 3 and 200 miles, and set forth a preference for U.S. fishing operations over the activities of foreign parties within that zone.

These actions had a tremendous impact on the development of western U.S. offshore fisheries. Figures 1a and 1b show the annual tonnage landed in west coast and Alaskan fisheries, respectively, since 1981, broken down by the mode of operation : domestic, joint-venture, or foreign. Both regions witnessed a progression from prominent foreign catcher/processor operations, through a period in which the growing domestic catcher-boat fleet supported joint ventures with foreign processing ships, to fisheries that are now wholly domestic. This transformation has been more dramatic in the fisheries off Alaska, in part because of their greater scale, but also because the west coast domestic fishery had already realized a higher degree of its potential by the mid-1970s.

This increase in domestic catching and processing has been accompanied by the entry of more vessels into the fishery. In 1981, fewer than 900 vessels landed groundfish (excluding halibut) off Alaska. By 1991, this fleet had soared to an all-time high of more than 2,200. The Alaskan halibut fleet numbered less than 2,900 in 1981, but reached 4,400 during the 1991 season (NPFMC, 1992b). The increase in fleet size has been less pronounced in the west coast fishery. However, fleet composition in both fisheries has shifted towards larger, more powerful fishing vessels over the past decade. This is particularly true in the Alaskan fisheries, where a substantial domestic factory trawler fleet has emerged.

The growth in domestic fleets has been accompanied by increasing fishery management problems. The west coast groundfish fishery has two major components : a trawl fleet which targets several different assemblages of species and a fixed-gear fleet whose major targets are sablefish and assorted rockfish species. Most west coast species are supplied primarily to domestic markets, with the exceptions of Pacific whiting and sablefish, which are largely exported to Japan. A major PFMC goal of managing the trawl fishery has been to extend the season as long as possible throughout the year, in order to stabilize employment opportunities and provide uninterupted supplies of product to regional domestic markets (PMFC, 1990). This has led to implementation of a complex system of trip landing and frequency limits for many economically desirable species. Even though the council has provided some flexibility for vessels of different sizes to meet the requirements, discarding of fish that exceed the limits has become a major concern. In a fishery that lacks any significant at-sea observer coverage, there is considerable uncertainty regarding the extent to which total removals from the fishery may be exceeding quotas or harvest guidelines. This method of management also imposes significant operating inefficiencies on the groundfish fleet.

Moreover, fishermen have repeatedly testified before the PFMC concerning the bitter irony of having to throw dead fish overboard at a time when allowable catches for many species are declining. The complexity of the regulations produces another nightmare for fishermen : simply complying with concurrent limits on several different species. Recent testimony by one enforcement official indicated that more than half of the landings which were checked for compliance were in violation of some landing restriction. In an effort to reduce some of this problem, the PFMC is experimenting during the 1992 season with a system of monthly limits for some species, which it is hoped will reduce the frequency of discard situations, as well as provide a transition to a system of transferable fishing rights.

In the fixed-gear fishery, where maintaining a steady supply of fish is less of a concern, the problem has been one of dramatically shortened seasons. Because sablefish are often caught in conjunction with other species, the PFMC has

resorted to use of trip limits for fixed-gear sablefish landings throughout much of the year in an effort to reduce discards of sablefish caught unintentionally. Prior to 1985, the only regulations affecting the sablefish fishery were limits on the amount of fish smaller than 22 inches that could be landed. During 1985, the season was closed in early December. By 1988, the season closed before September. During 1991, a 500-lb trip limit was imposed before June, and the fishery was closed entirely by July 1st (PFMC, 1991). After opening the 1992 fishery with a 500- and then 1,500-lb trip limits, unexpected high catch levels led to reduction of the limit to 250 lb prior to the start of the "open" season. The unrestricted season is expected to last less than one month this year, before trip limits are reinstated for the remaining duration of the fishery. This compression of the season has placed greater in-season monitoring demands on managers, and has significantly lowered the average income derived from this mainstay species.

The fisheries managed by the NPFMC utilize vastly larger stocks of fish, and provide a very high percentage of the resulting products, usually in frozen form, to Japanese and other foreign markets. Although steady employment opportunities are a concern of the council, it has not opted for a trip-limit style of management. Instead, both trawl and fixed-gear fisheries are managed principally by quota, with the use of multiple seasons in some cases. The trawl fishery is driven by more than 1.25 million mt of annual pollock catch, along with substantial harvest of Pacific cod and various flatfish species. As recently as 1988, the domestic fishery for pollock operated year-round (Kinoshita, et. al., 1991). By 1991, the open season had been split into two periods which totalled only 150 days of directed pollock fishing. In addition to quotas on groundfish species, harvests are limited by caps on the amount of prohibited species--such as halibut, salmon, and crab--that can be killed through incidental catch and mandatory discard. The mounting problems throughout the fishery have led the NPFMC to initiate analysis of a moratorium on new entrants to its fisheries, while a more comprehensive solution to over-capitalization can be developed.

Using quotas and season closures has also been the chief method of coping with overcapacity in the fixed-gear fisheries of the North Pacific. The halibut season in the Gulf of Alaska has been reduced from 128 days in 1975 to 20 days in 1980 to 2 days in 1991, despite a 3-fold increase in allowable commercial landings over the past decade (IPHC, 1977,1982,1991). The rapid rate of capitalization in the domestic sablefish fishery, reflected in a 50 % annual rate of increase in landings from 1981 to 1988, resulted in a similar decline in season length. During 1984, only one management sub-area had less than a 240-day season for sablefish ; and the season was open there for 6 months. By 1990, 2 of the 6 sub-areas had seasons of less than 3 weeks, while two others had openings of roughly 2 months. Together, those 4 areas accounted for nearly 90 % of the sablefish landed (NPFMC, 1991a).

Both of these management councils have struggled with the effects of overcapitalization, though they have generally appeared unwilling to take steps to remedy the underlying causes of the problem. Both councils have long histories of open access to groundfish fisheries which have engendered considerable philosophical opposition to the notion of selectively limiting access to the fish resource. What follows is a brief discussion of recent proposals for limiting entry to these groundfish fisheries, along with an evaluation of the role which economic analysis, and other factors, played in their development.

## 3. LIMITED ENTRY IN THE PFMC GROUNDFISH FISHERY

The PFMC embarked on its journey towards limiting entry to its groundfish fishery in the spring of 1987 (PFMC, 1992). At that time a group containing supporters and opponents of limited entry was formed, and given the charge to develop proposals for instituting a license limitation plan for the groundfish fishery. Two proposals were submitted to the Council during the summer of 1988. Workshops were held that winter in order to disseminate information and receive further input from the fishing community. A survey was subsequently administered, in order to obtain more input from various segments of the industry. Following deliberation of the industry response, the Council elected to continue the development of a detailed limited entry package, under the guidance of a new committee that would include not only members of the industry, but also state and federal agency representatives. This group provided guidance to a 3-member team of staff having responsibility for analysis of the proposal [1].

Even though the original thrust of the limited entry discussion had been towards a license limitation proposal, the potential for use of individual transferable quotas (ITQs) was discussed within the committee forum. While some

1. The author served as a member of this analytical team from February 1990 through the completion of the project.

segments of the fishery appeared amenable to the use of ITQs, much of the trawl fishery presented some serious problems. Several modes of trawling in this fishery involve the coincident catch of a variety of species, which in many cases have fairly independent market values and stock dynamics. Most committee members harbored serious doubts as to whether an ITQ plan could be devised, in a timely manner, which would overcome highgrading and other discard concerns in a fishery where observers were not likely to become an integral part of most fishing operations. Since the primary objective was to develop a proposal that would encompass the entire fishery, ITQs were eventually included only as a discussion item in the analysis, and were not embodied in any specific alternatives for council consideration.

From the outset, it was clear that the process of defining a limited entry fleet was not tied to the notion of an optimally sized fleet. Members of the industry expressed their displeasure with any system that would attempt to realize reductions in vessel numbers through the use of qualifying criteria. They viewed a buy-back program for permits as the only acceptable method for removing, what they considered to be, reasonably active participants entirely from the fishery. Unfortunately, without Congressional intervention, the opportunities for implementing a buy-back program were not viewed as realistic. The National Marine Fisheries Service (NMFS) lacked the funding to initiate such a program, and provisions of the MFCMA prevented NMFS from imposing an industry-funded program on all fishery participants. This set of political and administrative circumstances led to the delineation of the Council's primary objective for a limited entry program : "to limit or reduce harvest capacity in the West Coast groundfish fishery." This objective was augmented with a dozen secondary objectives, addressing a variety of economic, social, administrative, and enforcement issues. Economic objectives included promoting long-term stability, increasing net returns, maintaining opportunities for vessel flexibility, and ensuring consumers a stable supply of products at reasonable prices.

A qualifying window was established, running from July 1984 through July 1988. Two major options affecting fleet size were considered. In one, any vessel that had caught groundfish with trawl, longline, or pot gear during this window would qualify for a permit. In the other, higher qualifying criteria were set so that the number of qualifiers within each gear group would approximate the size of the active fleet during 1987. These criteria were based primarily on the number of deliveries that were made over the course of the entire window, although vessels whose landed catch was in the top 15-20 % of those using the same gear could also qualify, even if they did not meet the number-of-landings requirement. Under the more restrictive option, other vessels with some window landings that did not meet the qualifying criteria would be granted temporary, non-transferable participation rights, to allow for a period of adjustment to the new system.

It was recognized early in the process that issuing unrestricted permits to vessels or owners would allow fleet capacity to increase considerably, through the replacement of existing vessels with larger, more powerful ones. Various vessel characteristics were considered as candidates for restricting increases in vessel capacity. A vessel-length endorsement was finally chosen as a means of limiting such increases. A vessel intended to replace a qualifying vessel could not exceed the original vessel's length by more than 5 feet. Vessel permits could be combined to accomodate transfer to larger vessels, as long as the total harvesting capacity of the smaller vessels was at least as great as that of the larger one.

Because the Council had limited the scope of the available alternatives to those having at least as many participants as were observed in a recent year's fishery, one normally important economic rationale for limiting entry--namely, gains in fleet efficiency and net national benefits--was more difficult to establish than it would have been with a smaller target fleet-size. Because of the size and profitability of this fishery, relative to others, it seemed unlikely that very many vessels would be newly constructed specifically to participate in it. Thus, in terms of long-run equilibrium fleet sizes, there seemed to be little efficiency advantage from the standpoint of preventing unnecessary investment in vessels. Existing fishery management has relied upon numerous measures aimed at reducing the efficiency of individual operations--foremost among these, trip limits--and the removal of these could yield increases in fleet efficiency, as well. But, conditions that would allow the relaxation of trip limits will not occur without an actual reduction in fleet harvesting capacity. The only scenario in which noteworthy efficiency gains might result from the plan involves the entry of so much capacity into the trawl fishery that trip limits would have to be totally abandoned--because the year-round fishery could not be maintained without limits that are so low that they would create more discards than landings. The resulting compressed fishing season could lead to lower prices through the loss of some markets, and seasonal gluts of product provided to others. On the other hand, the efficiency benefits of a license plan could be enhanced, were a buy-back program to become feasible.

Beyond the matter of efficiency, however, was the question of the economic health of traditional west coast fishery participants. Deteriorating conditions in regional salmon fisheries and increasing overcapitalization in the Alaskan fleet provide some support for the argument that new capacity may be drawn into certain segments of the groundfish fishery

in the near future. In large part, then, economic analysis was left to discuss issues such as firm stability and market power, and whether the permitted fleet would be geographically representative, and of sufficient diversity that available quantities of all species would be harvested.

In March, 1991, following an intensive year of refining alternatives, analysis, and public comment, the PFMC decided that the fate of small west coast vessels, many of whom had fished predominantly for salmon during the window, needed further study. Subsequently, options for extending the end of the window period and creating an exemption for landing small quantities of fish were analyzed. In the final package, a compromise was struck, in which only landings of at least 500 lb counted towards qualifying for a permit, but a portion of species quotas, based on historical performance, would be allocated to an open access fishery for longline and pot gears, and would be managed under very restrictive trip limits. Gears not included in the limited entry program, such as nets and line gear other than longlines would also fish under the open access fishery, but could have different restrictions placed upon them than those fishing with longlines and pots. The qualifying standards for each gear group were also cut in half from the original values selected to approximate the 1987 fleet size. The conjunction of these two new requirements left the number of permanent permits relatively unchanged in the fixed-gear fleet, and reduced the number of temporary permits dramatically. But in the trawl fleet, where very few trips yielded less than 500 lb, the number of permanent permits rose by about 10 %. The proposal in this form was approved by the PFMC in November 1991, and subsequently submitted to the Secretary of Commerce for approval. Federal action on this item is still pending.

As mentioned, the analysis included general comparisons between license and ITQ approaches on several issues. It was hoped that by gradually familiarizing the Council and members of the industry with the strong points of ITQs, some of the fear and uncertainty of this style of management could by defused. In part because of the actions of the NPFMC regarding sablefish and halibut, discussed below, and perhaps also because of the increased dialogue on the subject within the license analysis, the Pacific Council initiated an ITQ scoping process in November 1991. At their April, 1992 meeting they voted to proceed with the development of an ITQ package for sablefish and halibut caught with fixed-gear.

## 4. LIMITED ENTRY IN NPFMC SABLEFISH AND HALIBUT FISHERIES

The issue of limiting entry to NPFMC groundfish fisheries dates back to at least 1982, when discussions addressed the benefits of limiting entry to the halibut fishery (NPFMC, 1992a). In 1983, the NPFMC recommended to NMFS that a moratorium on further entry be imposed in that fishery. Despite the benefits that might have been realized by that proposed action, it was not approved, on the grounds that it did not include a clearly articulated a set of goals and objectives, along with a rationale for how the action would serve those interests. During this period, the NPFMC also received comments from fishermen requesting that action be taken to ensure that the sablefish fishery did not deteriorate along the same path as the halibut fishery. Although discussion of the issue continued, by 1985 the only substantive action that had taken was the allocation of sablefish between the major domestic gear groups. This action began a continuing history of ill-fated council attempts to alleviate problems associated with excess capacity, by allocating fish to politically favored user groups.

In December of 1985, the NPFMC approved a cut-off date of September 26, 1985, which could be used to restrict the future access of those entering the sablefish fishery after the date. Subsequently, a committee was designated to review available options for addressing the fishery's problems and to contract for surveys of industry members, in order to evaluate support for alternative approaches. Following a request for input, the NPFMC received 59 separate proposals addressing sablefish management, reflecting the fragmented political nature of the fishery. Subsequent public workshops in 1988 and 1989 identified some general regional preferences for ITQs, license limitation, or continued open access management. By November, 1989 a draft analysis of 4 major alternatives had been prepared, and was released for public review. At its following meeting the NPFMC voted to move forward with a comparative analysis of ITQs (referred to as IFQs in NPFMC documents) and continued open access.

Although final action was scheduled to be taken on this issue at the June, 1990 meeting, the Council's inability to reach a clear concensus on the issue led to a series of further analyses for modifications to this original proposal. During this timeframe, a related proposal to institute ITQs in the halibut fishery was developed (NPFMC, 1991b), and eventually merged with the sablefish proposal, after some council members expressed a preference for dealing with the related matters in a joint action. Final action had been scheduled on the combined proposal for September, 1991, however the

vote was delayed until the December, 1991 meeting, at which time the proposal passed by a narrow margin. Subsequently, the matter was returned to the council's agenda for its meeting in April, 1992, where it voted not to reconsider its earlier decision, again by a narrow margin.

The evolution of the alternatives in the North Pacific discussion has, like those in the Pacific Council, been greatly influenced by "political realities" and the acceptibility of the alternatives to segments of the industry. Theoretically, ITQs allow for a gradual rationalization of the fleet, with the potential for providing compensation to those members of the fleet who elect to leave the fishery. The economic analysis of the alternatives provided as thorough a discussion as available data allowed of the comparative profitability of various sizes of vessels, in each of the management sub-areas for which quota is assigned. These measures of profitability were used to infer the most likely long-run fleet composition in each area, and the implications for equilibrium fleet size. Sensitivity analysis was conducted to assess the impact of cost reductions or increases in price that might result from implementing ITQs. The analysis also compared the impacts of different weighting schemes on the distribution of individual ITQ holdings, further comparing those values with actual landings amounts in the 1989 fishery.

Throughout the refinement of alternatives, communities supported by small-boat fleets expressed considerable concern over the likelihood of large freezer-longliner vessels buying up area quotas and removing one of their more important means of economic sustainability. This fear persisted even after the analysis indicated that these larger vessels were not likely to generate the highest rate of profit per pound of fish in several of the management sub-areas. Concern was also voiced over the possibility of harvest rights becoming controlled by speculators and other non-participants, in turn, leaving future fishermen to toil as sharecroppers. In yielding to these fears, the Council placed numerous restrictions upon the ownership and transferability of ITQs.

In an effort to prevent outside interests from gaining control of the fishery, the Council required that ITQs could only be owned by individual persons, and that in order to buy quota, an individual would have to have a minimum level of experience in Alaskan groundfish fisheries as a captain or crewman. Another major restriction on transferability limited the future use of ITQs to vessels in the same class as the vessel which landed the qualifying poundage for the person originally issued the ITQ. For this purpose, vessels were divided into three groups for sablefish : catcher-boats under 60 ft, catcher boats over 60 ft (generally under 100 ft), and freezer longliners (generally over 100 ft). The halibut plan further divided the group under 60 ft into two classes with a 35 ft dividing line.

The proposal also included limitations on the amount of quota an operation could control. Individuals could not own more than 1 % [1/2 %] of the overall quota for sablefish [halibut]. Similar percentage restrictions were also included for selected management sub-areas for both species. As a further limit on industry concentration, the percentages of the overall quotas that could be landed with any boat were restricted to the same levels as for ITQ ownership. A significant restriction on the use of ITQs necessitated that an owner of quota be aboard a vessel while it was fishing his ITQ, in order for the fish to be counted legally against his quota holdings at the time of landing. Additionally, quota would have to be held before a trip for the entire amount of the trip. The ability to adjust ITQ holdings while at sea, to avoid the necessity of discarding, was not viewed by the Council as preferable to a 5 % limit on overages for a trip, with a subsequent reconcilliation. The sum of these restrictions may be expected to have a considerable effect on the long-run efficiency of the program.

In fairness, it should be pointed out that both the sablefish and halibut fisheries would benefit greatly from implementation of even the very restrictive proposal that was approved in December, 1991. By increasing the quality of handling and the opportunity to market fresh halibut throughout the year, ex-vessel revenues would be expected to rise by 30 %. Without the pressures of a 1-day opening, harvesting and processing costs would also likely drop, resulting in an even greater net benefit to fishermen and processors. The sablefish fishery provides product predominantly for Japanese consumers, whose demand is largely seasonal, during the winter months. In previous years when Japanese fishing was allowed, harvest was concentrated at the end of the calendar year. The current spring fishery necessitates at least 6 months of storage for most of the product that is exported. Allowing fishermen to schedule sablefish fishing later in the year would reduce the cold-storage holdings, and also have a modest favorable impact on fish quality and size (Hastie). Together, these factors might represent about 10-20 % of the current ex-vessel value of the annual harvest. American fishermen and processors would be in a good position to capture a large share of this savings.

One of the more interesting aspects of this proposal's development has been the extent, and vigor, with which fishery participants objected to an offer that is as close to a compensated pareto improvement as we are likely to experience in fisheries management. People sincerely objected to having the option to sell their interest in the fishery to the highest

bidder. Admittedly, some recent entrants to the fishery may not have qualified for as much poundage as they were expecting, or hoping, to catch in the future. However, with significant increases in net return per pound, even many of the people receiving lower poundage might expect to receive comparable profit from their ITQ holdings. The overriding factor in this dissention appears to be tied intrinsicly to the issue of maintaining the way of life in small coastal communities ; making sure that their residents have at least some continuing access to the fishery. For example, a report prepared for industry interests in southeast Alaska suggested that poor rural fishermen would be "more likely to sell their quota shares (out of necessity) than their high income urban neighbors." Similar concern is expressed in the report over the rural poor's access to capital markets, for acquiring ITQs. One is left to speculate as to whether these people would be better off facing the same necessities during the 11 months of the year when these fisheries are closed, without having the asset of their ITQ holdings. Such concerns over the future viability of rural life in Alaska are important, to be sure. But, none of the ITQ proposals presented for council action over the past two years would prevent the State of Alaska or any municipality from helping, in some way, to underwrite the cost of acquiring quota by people in these communities. Given these concerns, it is interesting that much of the criticism of the ITQ plan also centers around the economic windfall that would be provided to those receiving quota. While an auction-based system for allocating harvest rights would be desirable, from the standpoint of recapturing resource rents from the public resource, such charges are not currently compatible with the MFCMA.

## 5. SUMMARY

Discussion of the need for limiting entry in the fisheries is often spearheaded by economists. Within the arenas of the Pacific and North Pacific Fishery Management Councils, economists have played an important role in stimulating the discussion of various limited entry options as more comprehensive approaches to solving both emerging and mature management problems. Although some segments of the industry have embraced the general concept of limited entry, that support often withers in the face of specific proposals. Furthermore, a large portion of the industry continues to express the belief that competition, within an olympic style fishery, is the appropriate method of determining who belongs in the fishery and who doesn't. These participants often appear to place a higher priority on having the continuing opportunity to race for fish than on generating higher returns, either for the industry, in general, or themselves, in particular. Inevitably, where strong industry support is obtained, it is received only after conditions in the fishery in question degenerate to such an extent that the alternative mangement measures needed to cope with them become unbearable to a majority of the fleet.

One might envision a system of management wherein policy makers would identify problems in the fishery, define a set of objectives for potential solutions to the problems, and then allow a team of technical advisors, including economists, to outline the most effective means of achieving those objectives. In the management of western U.S. fisheries, it is much more common for alternative actions to be delineated by council members, often before a clear and complete statement of the problem has been articulated. As a result, the role of the economist in the development of fishery policies, such as limited entry, is less one of analyzing problem situations, and devising solutions for them, than of analyzing the likely effects of preconceived solutions to ambiguously stated problems.

Throughout the process of transforming western U.S. fisheries into domestic ventures, additional fish could often be transferred from foreign allocations, so that newcomers did not significantly reduce the amount of fish available to existing domestic users. Having exhausted this buffer, and with it the opportunity to continually increase the size of the domestic "pie", the fishery management councils in this region have been asked with increasing frequency to allocate fish between competing domestic users. Even though these allocation issues consume massive amounts of council, committee and research time, the councils are reluctant to bequeath their allocation authority to the marketplace. Some of this hesitence undoubtedly stems from the fact that most council members represent specific interest groups. Agreeing to a market-based solution to allocation would place each member in the position of forfeiting much of his future ability to help his constituency via accustomed political channels. Because no one is certain how the distribution of fishing rights would evolve under ITQs, all members become more cautious. Often, by the time a political concensus can be forged among the various factions participating in the fishery and the management dialogue, a proposal is watered down by concessions to the point where comparatively few of the stated objectives, particularly the economic benefits, can be realized.

An outside observer would surely wonder whether this method of management produces policies that are in the best interest of the general public, to whom the resource rightly belongs. The problems embodied in current management are not new, having been addressed by James Madison at the inception of the United States.

He continues by noting that the only relief from the tyranny of such factions lies in principal of the republic, and its representative form of government. Within the present Council structure, there is neither the effort to insure that those who serve do not have ongoing financial interests in the fishery, nor recourse by the general populace to elect new representatives to such bodies should their decisions, or lack thereof, stray far afield from the common good. Since neither the present Council structure nor existing over-capacity problems are likely to be remedied in the near future, it would appear that management policy in the western U.S. fisheries will continue to be shaped principally by the strongest industry groups, leaving management economists with a narrow and often ineffective role in solving the many problems faced by these fisheries.

The most common and durable source of factions has been the verious and unequal distribution of property... The regulation of these various and interfering interests forms the principal task of modern legislation and involves the spirit of party and faction in the necessary and ordinary operations of the government... It is vain to say that enlightened statesmen will be able to adjust these clashing interests and render them all subservient to the public good. Enlightened statesmen will not always be at the helm. Nor, in many cases can such an adjustment be made at all, without taking into view indirect and remote considerations, which will rarely prevail over the immediate interest which one party may find in disregarding the rights of another or the good of the whole (Hamilton, 1961).

# Exvessel Price Behavior in West Coast U.S. Groundfish : Implications for the Choice of Fishery Management Technique

**Susan Hanna** *

Department of Agricultural and Resource Economics, Oregon State University Corvallis, Oregon 97331, USA

ABSTRACT

*The objective of this paper is to examine the interaction of the exvessel market with the fishery harvest sector and analyze implications of this interaction for the choice of fishery management technique.*

*Historical trends in exvessel prices for several groundfish (demersal) species are illustrated. The structure of the exvessel market is detailed, including price negotiating processes and tie-in sales. Estimates of price flexibilities and elasticities are presented. Major factors influencing the responsiveness of groundfish prices at the exvessel level are identified, including fluctuations in exchange rates and substitution relations with nonseafood commodities. The role played by market factors in driving fishing effort is discussed.*

*Fishery management in West Coast U.S. groundfish is at a juncture. Established management techniques of gear regulations and trip quotas are under reexamination. New management approaches of license limitation and individual fisherman quotas (IFQ's) are being considered. A major concern of industry representatives is to assess the impact of each management technique on the structure and function of the exvessel market. The historical behavior of exvessel groundfish prices carries implications for the impact each type of management technique is likely to have on the harvest sector. These implications are discussed.*

* This publication is the result of research sponsored by Oregon Sea Grant with funds from the National Oceanic and Atmospheric Administration, office of Sea Grant, Department of Commerce, under Grant No. NA85AA-D-SG095 (project no. R/ES-13) and from appropriations made by the Oregon State Legislature. The provision of unpublished data by Jim Hastie and the review comments of David Brooks are gratefully acknowledged.

## 1. INTRODUCTION

This paper presents an overview of exvessel prices for two major West Coast groundfish species : rockfish (*Sebastes* spp.) and Dover sole (*Microstomus pacificus*). These species are the "bread and butter" species of the mixed groundfish landings, constituting the bulk of the quantity landed in any given year. Price and landings data are available in various sources for various time periods. Major data sources are the PacFIN Management Data Base, state fishery agencies, and the Fisherman's Marketing Association. Data from these sources are summarized in the "Economic Status of the Groundfish Fishery" reports published annually by the National Marine Fisheries Service Southwest Region and in various reports of the Pacific Fishery Management Council.

The discussion is divided into 5 sections : 1. Price series of rockfish and Dover sole ; 2. Exvessel price correlations for major groundfish species ; 3. Price-quantity relationships ; 4. Price response relationships ; 5. Implications of rockfish and Dover sole price behavior for choice of fishery management technique.

## 2. PRICE SERIES

Series of nominal exvessel prices for West Coast groundfish show a marked and continual upward movement since the 1970's for Dover sole and rockfish (Figure 1). Embedded in the nominal time series is a general price inflation which distorts the true direction of change in exvessel prices. Time series adjusted for the effects of inflation reveal a different pattern of change. The series of real prices for Dover sole and combined rockfish (Figure 2) shows a cyclic pattern that is repeated for each species between 1962 and 1988. Real prices for these species rose and fell in four cycles : 1963-1971 ; 1971-1976 ; 1976-1981 ; 1981-1988. In general, each cycle occurred at a slightly higher price level than the previous one, resulting in a slight increase in average real price from one cycle period to the next. The exception to this trend is a $.01 decline in the average real price of Dover sole between the 1976-1981 period and the 1981-1988 period.

West Coast groundfish prices show different degrees of seasonal variability. Trawl gear prices are influenced by negotiations between processors and the Fisherman's Marketing Association (FMA). These negotiations establish market orders specifying minimum exvessel prices to be received by FMA members over a specified time period. As such, prices for most groundfish species tend to be fairly stable within a market order period, typically about six months. However, the stabilizing influence of the FMA price does not always dampen coastwide exvessel price variation over seasons or areas. Current work in progress with data on FMA market order prices is expected to yield insight into the role FMA prices play in influencing price levels and directions of change for all West Coast groundfish prices.

Price differences by size are not an important element in the exvessel price of most West Coast groundfish. Sablefish (*Anoplopoma fimbria*) is the notable exception. In 1987 and 1988, exvessel price ranged from $.33 to $.45 per pound between large and small sablefish caught by trawl gear. In that time period, the price difference by size was even greater for longline caught sablefish, ranging from a $.43 to a $.46 per pound difference between large and small sablefish (Hastie 1989).

## 3. PRICE CORRELATIONS

Correlations between exvessel prices of Dover sole and rockfish and other major West Coast groundfish species are reported in Table 1. As with the nominal price series, correlations of nominal prices show a strong relationship that includes the general inflationary trend in prices over the time period. Adjusting for the inflationary trend reveals interesting differences in the strength of association between various species exvessel prices.

Not surprisingly, the highest correlations between exvessel prices exist for species of similar characteristics. Real prices for flatfish species (Dover sole, English sole, Petrale sole) are strongly related : correlation coefficients (R's) range between 87 and 93. Roundfish species (combined rockfish, widow rockfish, sablefish) show similar strong associations : correlation coefficients range between 62 and 99. An interesting exception to the general pattern of stronger associations among species of similar type is the high correlation between Petrale sole price and widow rockfish price (R =.9).

## 4. PRICE-QUANTITY RELATIONSHIPS

Plots of real prices and quantities landed of rockfish and Dover sole (Figures 3-4) exhibit some interesting patterns. Rockfish exvessel price and quantity were stable between 1971, followed by a period of increase in both exvessel price and quantity landed. Between 1980 and 1985, price and quantity of rockfish showed an inverse relationship : quantity landed peaked in 1982 ; real prices were at their lowest level in 1981 followed by a steady climb until 1988. Between 1982 and 1986 the quantity of rockfish declined, followed by a steady two year period between 1986-1988. The quantity of rockfish landed becomes constrained by regulation to an increasing extent after 1983. By 1986 landings of several rockfish species had been stabilized at equilibrium yield levels.

Real exvessel price and quantity landed of Dover sole generally move in the same direction between 1971 and 1980, changing to an inverse relationship between 1984 and 1987. Unlike rockfish, regulations have not played a direct role in limiting Dover sole landings until very recently. Direct restrictions still do not apply to Dover sole by itself, but beginning in 1991 restrictions were applied to the deepwater complex from which Dover sole is taken in order to limit harvest on sablefish and other associated species (Pacific Fishery Management Council 1991). However, market factors do play an important role in limiting landings. Dover sole are not considered high quality flatfish and as such face limited markets. Limits placed by groundfish processors on size of Dover sole landings remain the most important factor affecting quantities landed.

## 5. PRICE RESPONSE RELATIONSHIPS

A set of fundamental questions regarding exvessel prices of groundfish have to do with the responsiveness of species price to changes in other factors. Of particular interest for policy and market analysis is the responsiveness of species price to changes in the quantity landed, changes in quantities of available substitutes, and changes in prices of substitute species. The responsiveness of prices to changes in quantities landed or other factors is called price flexibility.

Price flexibility equations have been estimated for the two major groundfish species, rockfish and Dover sole. Initial estimations have been made using 26 years of data on landings and prices. The time period covered by these data encompasses a major change in institutional arrangements for the fishery brought about by the passage of the Magnuson Fishery Conservation and Management Act (MFCMA) of 1976. Accordingly, estimations were made for two time periods : the entire 1962-1988 time period and the 1977-1988, post MFCMA, period.

For the longer time period, four equations were estimated using annual observations (Table 2). Two equations each were estimated for Dover sole and rockfish. One set of equations estimated each species' real exvessel price as a function of own quantity landed, substitute species quantity landed, and real per capita disposable income. A second set of equations estimated real exvessel price as a function of own quantity landed in the previous year, substitute quantity landed in the current year, and real per capita disposable income. For the shorter time period, for which data on imports of Canadian groundfish were available, four additional equations were estimated incorporating imports of Canadian cod and flatfish.

Results of the estimations without imports are reported in Table 3. In general, the equations estimated for the 1977-1988 time period (equations with subscripts n) have better fits than those estimated for the longer time period. The rockfish equations have better fits than equations estimated for Dover sole. The rockfish equation with the best fit is, for each time period, rockfish price as a function of own quantity landed in the current time period and other factors (Equations $R_1$ and $R_{1n}$). The Dover sole equation achieved the best fit for the 1977-78 time period when price was estimated as a function of lagged own quantity and other factors (equation $D_{2n}$).

Canadian imports of groundfish are anecdotally identified as substitutes for West Coast groundfish. Price response equations including imports of Canadian flatfish and Canadian roundfish are presented in Table 4. Both current year and lagged year own quantity equations are estimated. The addition of an import variable improves the overall fit of the estimation in all cases, but the coefficients for import quantities do not have the expected negative sign.

Price flexibility to landings measures the sensitivity of a species price to the quantity of that species landed. Price flexibility coefficients are expected to have a negative sign, illustrating an inverse price/quantity relationship. Prices are called flexible if the price flexibility coefficient has an absolute value greater than one : this means that for every 1 % change in quantity landed, prices change by greater than 1 %. Price flexibility coefficients with values less than one indicate an inflexibility of prices to changes in own quantities landed.

Price flexibility to own landings is calculated as :

$$F_{p1} = \frac{\partial p}{\partial q} \cdot \frac{\bar{q}}{\bar{p}}$$

Price-landings flexibility coefficients calculated from regression equation coefficients ($\delta p / \delta q$), mean price ($\bar{p}$), and mean quantities ($\bar{q}$) are displayed in Table 5.

Seven of the eight flexibility coefficients for own price ($R_1$, $R_2$, $D_1$, $D_2$, $R_{1n}$, $R_{2n}$, $D_{1n}$, $D_{2n}$) have the expected negative sign. In contrast, because the coefficients on import quantities have positive signs, import price flexibility coefficients have positive signs. All flexibility coefficients have absolute values less than one, indicating an inflexibility of real exvessel prices of both rockfish and Dover sole to changes in own quantities landed over the two time periods. For example, the flexibility coefficient of -.56 measured for Dover sole ($D_{2n}$) indicates that a 1 % increase in Dover sole landings will result in only a.56 % decrease in Dover sole price.

Import price flexibilities have lower values than own price flexibilities for the same time period, indicating a lower degree of response in domestic groundfish prices to changes in import quantities than to changes in own quantities. The positive sign of the import price flexibilities is counter-intuitive, indicating that changes in quantities of groundfish imports are associated with changes in domestic groundfish price of the same direction. This relationship is in direct contradiction to widespread anecdotal evidence. It is generally accepted that under favorable price conditions Canadian groundfish is substituted in West Coast processing lines for domestic groundfish, leading to lower prices offered to West Coast groundfish fishermen. The degree of acceptance of this general knowledge leads to the conclusion that problems may exist with the equations as currently specified.

Price flexibility values for Dover sole and rockfish are consistent with the range of values reported for other groundfish by Wang (1985), Bockstael (1977), and Crutchfield and Gates (1982). Own price flexibilities are higher for the 1977-1988 period than for the 1962-1988 period, reflecting a period of the fishery with more developed markets and more players in the market. Values of import price flexibilities for 1977-1988 are consistent with those of own price flexibilities for the period 1964-1988.

Price response equations for West Coast sablefish landed by fixed gear (longline and pot) have been estimated by Hastie (1989). The market for sablefish landed by this gear type is primarily a Japanese export market. Nominal fixed-gear exvessel price is estimated to be a function of lagged own price, Tokyo Central Wholesale Market price, and the exchange rate. The importance of the export market for this species caught by fixed gear is reflected in the $R^2$ of.84 for the estimated equation. Price flexibility with respect to the exchange rate has an estimated value of -.8. This value suggests an almost unit flexibility of exvessel fixed-gear price to changes in the exchange rate ; i.e.a 1 % increase in the exchange rate will lead to an almost equivalent decrease in exvessel price. Hastie's results also suggest that over time the Japanese market has played an increasingly influential role in the formation of West Coast fixed gear sablefish prices.

## 6. IMPLICATIONS FOR CHOICE OF MANAGEMENT TECHNIQUE

Work is continuing to establish as full a picture of the West Coast groundfish price structure as the data will allow. Work to date has established several important basic attributes of this price system which have implication for the choice of management technique. Prices show seasonal variations to varying degrees but because of the price negotiating system are relatively stable. Real prices of groundfish have both increased and declined over the past 12 years at the exvessel level. Strong correlations exist between exvessel prices of species of similar type, but weaker correlations exist between exvessel prices of species of different types. Exvessel prices of two major West Coast groundfish species are fairly inflexible to quantities landed and to quantities imported.

Management of the West Coast groundfish fishery has become increasingly complex over time, moving from an olympic system of landings within overall annual quotas to a modified olympic system within trip quotas. "Trip limits" are established for several groundfish species to limit both the quantity and frequency of landings and to space landings throughout the year. Because targeting takes place on multispecies assemblages, trip limits indirectly limit landings of associated species and/or result in discards at sea of limited species when fishing continues in the same biological assemblage.

The exvessel market effect of trip limits is twofold : variability in quantities landed is dampened through upper limits per unit of time placed on certain species ; fishermen control of the timing of quantities landed is diminished. For example, fishermen cannot forego targeting a species until late in the season in order to take advantage of more favorable market conditions because they will face the same or even greater restrictions on landings later in the season than early.

Regulatory trip limits are supplemented by limits placed on landings of certain species by processors. Processors may direct vessel captains before a trip begins to bring in only certain combination of species and may also specify quantity limits of species combinations. The effect of these combined limits is to place the balance of exvessel market power with processors, a further contributor to low flexibilities of price response to quantities landed. Processors are in a position to absorb the effects of favorable market conditions through increases in exvessel-wholesale margins without passing price increases on to fishermen.

Changes in the regulatory system for West Coast groundfish offer the potential for a freer functioning exvessel market which would be reflected in increased price flexibilities. A license limitation program has been developed for the three major groundfish gears : trawl, longline and pot. This program, on the verge of implementation, has the potential to increase market power of fishermen only in the long run as effort reduction strategies slowly take effect. However, in conjunction with the license limitation program, individual quota (IQ) systems are also under consideration for several groundfish species. IQ systems have the potential to place more control over timing and composition of landings in the hands of fishermen. The design and the nature of implementation of IQ systems in this fishery will be critical factors in the extent to which fishermen market power increases. For example, if IQ's are layered over existing trip limit systems, a major benefit of such systems in terms of increased flexibility of fishermen choice in landings will be removed.

# Multiproduct Supply under Production Quota : an Application to Pacific Fisheries

**Dale Squires** *

National Marine Fisheries Service, Southwest Fisheries Science Center, P.O. Box 271 La Jolla, California 92038 USA

ABSTRACT

*This paper uses the concept of virtual prices to evaluate the competitive multiproduct firm's output supply when faced with production quotas. The properties of the quota-regulated and unregulated output supply functions are related, consistently describing behavior under both regimes. The impacts of quotas upon multiproduct costs, shadow prices of fixed factors, and multiproduct capacity utilization are also analyzed. The effects of imposing production quotas are empirically evaluated for an open-access multiproduct fishing industry and the implications for regulation assessed.*

## 1. INTRODUCTION

Production quotas are a well-established method to regulate output flows in a number of industries. One of the crucial problems facing regulators when designing and implementing a quota scheme is anticipating the multiproduct firm's supply behavior in response to changes in quota levels and market conditions under the new regulatory regime. Over a longer time period, the quota and induced reorganization of the product bundle may also change the firm's investment behavior and ultimately the industry structure.

Neary and Roberts (1980) considered the related problem of household behavior under rationing, and related the properties of rationed demand functions to the properties of the unrationed demand functions with the latter evaluated at the virtual prices. This approach has not been used to analyze firm supply behavior.

* The author is grateful to Stan Metcalfe for helpful discussions and to Mohammed Alauddin, Boris Bravo-Ureta, Christopher Bliss, Larry Jacobsen, Jim Kirkley, Alistair McIlgorm, Ricardo Quiroga, and two anonymous referees for detailed comments and to Pete Leipzig of the Eureka Fisherman's Marketing Association for identifying vessels with high-speed winches. The author alone, however, remains responsible for any remaining errors. The results are not necessarily those of the National Marine Fisheries Service. The author is grateful to the Department of Economics, University of Queensland, where this paper was written.

This paper *ex ante* evaluates the competitive multiproduct firm's supply response facing a production quota. The behavioral hypothesis of revenue maximization and a production quota are applied but the extension to another behavioral hypothesis or an input control is immediate. The framework of Neary and Roberts and virtual prices is used to relate the properties of quota-regulated and unregulated input-compensated (Hicksian) supply functions, consistently describing behavior under both regimes. This framework is also applied to relate the unregulated and regulated firm's investment incentives, as signaled by measures of multiproduct capacity utilization and shadow prices of quasi-fixed factors.

The paper addresses the design of a command-and-control output quota in an open-access multiproduct fishing industry prior to its regulation by a production quota. To curtail excessive production and depletion of sablefish, which has an important export market to Japan, a catch quota for the entire industry is set each year. Year-round production is achieved by limiting the amount of sablefish caught during each firm's fishing trip. Regulators routinely make adjustments during the year to these trip quotas as information accumulates about the actual level of catch as opposed to the target industry quota. Regulators are often unsure about the firm's supply response under the quota, and hence do not know to what extent the proposed adjustments alter production. If firms do not sufficiently curtail production, the industry quota is prematurely exhausted. The fishery is then shut down prior to year's end, causing severe financial hardship. The quota might also induce spillover harvesting onto other threatened resource stocks and perhaps excessive depletion, requiring supplementary quotas.

Markets and prices also change over the year. If the supply response under regulation is sensitive to price changes, sizable product transformations onto unregulated species with threatened resource stocks again could require supplementary quotas.

A quota and its marginal adjustments may also affect the firm's investment behavior. Quota may cause the multiproduct firm to adjust its volume and mix of production, in turn altering incentives for investment or disinvestment (Segerson and Squires, 1993). Evaluating these effects helps to design quota schemes consistent with the overall objectives of the regulatory program. For example, in this fishery, the quota is intended to only spread production throughout the year but not to create investment disincentives severe enough to induce full-time producers to exit the industry. Regulators must also consider these potential problems when adjusting quotas.

In short, regulators must design the quota consistent with the overall limits established by the resource stock and with the currently unregulated multiproduct firm's technology and multiproduct investment incentives when all outputs are decision variables.

The approach used in this paper should be useful not only for fisheries regulation, but also in connection with any multiproduct firm or industry facing output constraints. Production controls are often applied to regulate firms exploiting other common property resources or to limit a particular output for health or environmental reasons. In agriculture, forestry, transportation, and financial and health services, production controls are routinely applied. Market economies emerging from centrally planned economies are a blend of markets and quantity controls. Finally, in the context of international trade and GNP functions, the approach could be used to analyze the effects of export quotas or voluntary export restrictions.

Section II develops the empirical model, Section III examines the empirical results and implications for regulatory policy, and Section IV contains concluding remarks. The Appendix summarizes the main results for multiproduct supply under production quota.

## 2. EMPIRICAL MODEL

### *2.1 Industry background*

The potential effects of a quota upon sablefish production were studied for an open-access multiproduct trawl fishery off Northern California and Southern Oregon of the United States. The three ports are Eureka, Crescent City, and Brookings. This region is one of the centers of the sablefish fishery on the Pacific coast, which is conducted in the deep waters of

the continental slope, beginning at a depth of about 200 fathoms. Vessels harvest two other important species on the continental slope, Dover sole and thornyheads. Several other species are also harvested in shallower waters to utilize excess hold capacity and to enjoy product diversity.

When serious fishing began on the three continental slope species about a decade ago, their stocks were virtually unexploited but were subsequently fished down to about maximum sustainable yield (MSY) levels, at which they currently rest. Overcapitalization of the fleet and growing sablefish export demand from Japan, coupled with the absence of property rights, created harvest pressures sufficient to potentially deplete the stock of this slow-growing and long-lived species. Command-and-control quotas on sablefish for individual fishing trips were considered to maintain stocks close to MSY levels. The goals were to prevent overproduction, conserve the resource stock, maintain a year-round fishery, and increase economic rent.

### *2.2 Production process*

The analysis assumes that the unregulated firm maximizes profit in two stages. In the first stage of production, a fishing trip, a vessel departs port toward a pre-selected fishing ground. The net is released, towed for several hours off the bottom, hauled in, its contents released onto the deck, sorted by species, and then stored in ice in the hold. Species composition can be altered by changing the area fished or depth and speed of net tow.

Vessel operators key production directly to the market (fish brokers or processors), given relative prices and the technological constraints imposed by the vessel, gear, equipment, weather, and resource abundance. The gear type, design, and size of the vessel largely determine the level of other inputs on the trip, including labor and fuel consumption. Moreover, inputs on the vessel are largely fixed because boats are away at sea where input levels cannot be readily altered. The services of some inputs, particularly fuel, may vary with time at sea during an individual fishing trip, but time at sea varies only slightly and the variation is not systematic. The narrow width of the continental shelf and slope (limiting fishing area), limited hold (storage) capacity, and relatively small vessel sizes limit trip lengths to a maximum of about five days. Hence, the input bundle can be specified as a single, composite input, since vessel size or capital stock is fixed over such a short production period and largely determines the level of other inputs. Formally, Leontief input separability is assumed, with input quantities remaining in fixed proportions over time.

Revenue maximization subject to a single quasi-fixed input is the appropriate behavioral objective for a such a short production period once a resource stock area has been determined (Kirkley and Strand 1988 ; Segerson and Squires 1993). The composite input is proxied by vessel size, gross registered tons (GRT).

In the second stage of production, over roughly three to fourteen months, firms adjust the level of their capital stock to minimize production costs by selecting the optimal vessel size.

The analysis studies vessels less than 75 GRT (a segment of the fleet not previously studied) which landed at least 1,000 pounds of sablefish in 1984. The last year without trip quotas was 1984. Only vessels with high-speed winches were considered, where these powerful winches allow vessels to exploit the deep waters of the continental slope.

### *2.3 Unregulated production*

The revenue-maximizing vessel-level production process for an unregulated fishing trip is modeled by the following nonhomothetic generalized Leontief revenue function (Kirkley and Strand) :

$$R[P, Z] = \Sigma_i \Sigma_j \alpha_{ij} [P_i P_j]^{1/2} Z + \Sigma_i \alpha_i P_i Z^2 + \Sigma_i \Sigma_k \beta_{ik} D_k P_i Z + \Sigma_i \Sigma_j \tau_{il} E_l P_i Z, \quad (1)$$

where $P_i$ is the price of species i, Z is the composite input, $D_k$ is the $k^{th}$ of two dummy variables for ports in Brookings and Crescent City, and $E_l$ is the $l^{th}$ of three quarterly dummy variables for winter, spring, and fall. The base case accounts for the port of Eureka in the summer. The area dummy variables $D_k$ account for spatial variations in access to fish stocks, species abundance, and port effects on prices. The quarterly dummy variables $E_l$ account for intertemporal variations in the technological constraints of weather and resource abundance.

The input-compensated supply equations Y[P,Z] for unregulated production obtained by Hotelling's Lemma are (McFadden 1978) :

$$\frac{\delta R\,[P,\,Z\,]}{\delta P_i'} = Y_i[P,\,Z\,] = \alpha_{ii}\,Z + \alpha_i\,Z^2 + \Sigma_k\,\beta_{ik}\,D_k\,Z + \Sigma_l\,\tau_{il}\,E_l\,Z + \Sigma_j\,\alpha_{ij}\,[P_j/P_i]^{1/2}\,Z\,, \tag{2}$$

where $Y_i$ is the quantity harvested of species i. Symmetry is imposed by the econometric restriction : $\alpha_{ij} = \alpha_{ji}$, i not equal to j. Zero homogeneity in prices for the supply equations follows from the generalized Leontief functional form.

### *2.4 Technology Tests*

The effect of an output quota depends upon the final form of the technology, which can be assessed by likelihood ratio tests of parametric restrictions. Input-output separability implies a single aggregate input and output. The marginal rates of transformation between all output pairs are independent of factor intensities when the technology is separable between M outputs and the composite input. Hence, only the overall output, and not the individual outputs, requires a quota. The econometric restriction with the Generalized Leontief revenue function is (Kirkley and Strand) : $\alpha_i = 0$, all i.

A technology joint-in-inputs requires all inputs to produce all outputs. Separate production processes exist for each output as a function only of Z and $Z^2$ and not P when the technology is nonjoint-in-inputs. Because there are no technological or cost trade-offs between outputs, relative price changes or imposition of, or changes in, quota on one output do not spill over onto another output. The econometric restriction for nonjointness-in-inputs throughout the product set is written (Kirkley and Strand) : $\alpha_{ij} = 0$, i not equal to j, all i,j. Nonjointness-in-inputs for a single output, say $Y_1$ , requires $\alpha_{1j} = 0$, all j, j not equal to 1.

Pooling the data over quarters and ports can also be assessed by likelihood ratio tests.

### *2.5 Quota-regulated production*

Neary and Roberts showed, in the context of consumer demand, that the properties of rationed profit, revenue, or cost functions and their derivative demand or supply functions can be related to the properties of the quota-constrained functions, where the latter are evaluated at the virtual prices. Virtual prices, $q^-$, first developed by Rothbarth (1941), are defined as an implicit function of $Y^-$, P, and Z by the restriction that they are those prices which would induce an unregulated firm to produce that quota level $Y^-$ :

$$Y^- = Y[P\hat{}q^-,\,Z], \tag{3}$$

where $P\hat{}$ is the price vector of unregulated outputs and Y is the vector of input-compensated supply functions for the regulated products evaluated at the virtual prices. In single-product production, the virtual price equals marginal cost and the marginal cost curve equals the inverse supply function. In multiproduct production, marginal costs assume all other outputs are fixed in quantity, while the supply curves assume that all other outputs are at their respective optimal levels. Hence, inverse marginal cost curves and supply curves coincide only at the initial optimal point. (Beattie and Taylor 1985) In contrast, virtual prices, because they are a function of $P\hat{}$ and input prices, incorporate all adjustments in the unregulated outputs and inputs to their respective optimal levels at optimal output and input mixes and levels other than the initial. See Neary and Roberts for a formal definition and proof of existence.

The virtual price for the sablefish quota $q^-$ is estimated from the corresponding unregulated supply equation of (2). If sablefish is indexed as 1 and the remaining five outputs (species) are indexed 2 - 6, and the sablefish quota is $Y_1 = Y^-_1$, then the virtual price for sablefish $q^-_1$ is (where $\Omega = \Sigma_k\,\beta_{1k}\,D_k\,Z + \Sigma_l\,\tau_{1l}\,E_l\,Z$) :

$$q_1^- = \left[\frac{\Sigma_{j=2,\,\ldots,\,6}\,\alpha_{1j}\,P_j^{1/2}\,z}{Y_1^- - \alpha_{11}\,Z - \alpha_1\,Z^2 - \Omega}\right]^2. \tag{4}$$

At the quota-regulated production point the rationed and unrationed supply functions are equivalent provided the latter are evaluated at the virtual prices. The quota-constrained input-compensated supply functions for the unregulated outputs (indexed 2,...,6) are derived by substituting (4) into (2) to give :

$$Y_i^- = \alpha_{ii} Z + \alpha_i Z^2 + \Sigma_k \beta_{ik} D_k Z + \Sigma_L \tau_{il} E_l Z + \\ + \Sigma_{j=2,\ldots,6} \alpha_{ij} [P_j/P_i]^{1/2} Z + \alpha_{i1} \left[ \frac{\Sigma_{j=2,\ldots,6} \alpha_{1j} P_j^{1/2} Z}{(Y_1^- - \alpha_{11} Z - \alpha_1 Z^2 - \Omega)} \right] \left[ \frac{1}{P_i} \right]^{1/2} Z . \quad (5)$$

*2.6 Price elasticities of supply*

The input-compensated price elasticities of supply for unregulated production are written :

$$E_{ij} = \frac{\delta \ln Y_i}{\delta \ln P_j} = \frac{Z}{2 Y_i} \alpha_{ij} [P_j/P_i]^{1/2} \quad (6)$$

for i not equal to j, i, j = 1, ..., 6. The own-price elasticities are given by the homogeneity of degree zero of the supply equations : $E_{ii} = -\Sigma_j E_{ij}$, i not equal to j. $E_{ij} > / < 0$ indicates that outputs $Y_i$ and $Y_j$ are net complements / substitutes.

The input-compensated price elasticities of supply for regulated production when quota is binding are written :

$$E_{ij}^- = \frac{\delta \ln Y_i^-}{\delta \ln P_j} = \frac{Z}{2 Y_2^-} \alpha_{ij} [P_j/P_i]^{1/2} + \frac{\alpha_{i1} \alpha_{1j} Z^2}{2 Y_i^- (Y_1^- - \alpha_{11} Z - \alpha_1 Z^2 - \Omega)} [P_j/P_i]^{1/2} . \quad (7)$$

for i not equal to j and i, j = 2, ..., 6. Because of symmetry, $\alpha_{i1} = \alpha_{1i}$. The own-price elasticities of unregulated input-compensated supply when sablefish is under quota are given by the homogeneity of degree zero of the supply equations. $E_{ij}^- > / < 0$ indicates net complements / substitutes. $E_{ij}^- \leq E_{ij}$, i, j = 2, ..., 6 due to the Le Chatelier-type effect of a quota.

Changes in the prices of other regulated or unregulated products or the quantities of quasi-fixed factors do not alter quotas, since the binding quota is a fixed, perfectly inelastic supply curve to the firm. In addition, input-compensated supply for an unregulated product is unaffected by changes in the prices of quota-regulated outputs.

*2.7 Quota elasticity*

The elasticity of input-compensated output supply for the change in unregulated output with a change in quota level is :

$$E_{iY^-}^- = \frac{\delta \ln Y_i^-}{\delta \ln Y_1^-} = - \frac{\alpha_{i1} Y_1^- Z}{Y_i^-} [1/P_i]^{1/2} \left[ \frac{\Sigma_{j=2,\ldots,6} \alpha_{1j} P_j^{1/2} Z}{[Y_1^- - \alpha_{11} Z - \alpha_1 Z^2 - \Omega]^2} \right] , \quad (8)$$

i = j for $Y_i^-$ . $E_{1Y^-}^- > / < 0$ indicates net complements / substitutes.

*2.8 Investment Incentives*

Shadow prices of quasi-fixed factors ($W^*$) are investment determinants ; they represent the firm's implicit marginal valuation of the quasi-fixed factor. The shadow price measures the change in revenue from a marginal change in Z. It is given by :

$$\delta R[P ; Z]/\delta Z = W^* = \Sigma_i \Sigma_j \alpha_{ij} [P_i P_j]^{1/2} + 2 \Sigma_i \alpha_i P_i Z + \Sigma_i \Sigma_k \beta_{ik} D_k P_i + \Sigma_i \Sigma_l \tau_{il} E_l P_i . \quad (9)$$

The quota-constrained shadow price ($W^{*\bar{}}$) is given by substituting (4) into (9) to give :

$$W^{*\bar{}} = \alpha_{11} 2\left[ \frac{\Sigma_{j=2,\ldots,6} \alpha_{1j} P_j^{1/2} Z}{Y_1^{\bar{}} - \alpha_{11} Z - Z - \alpha_1 Z^2 - \Omega} \right]^2 + \Sigma_{i=2,\ldots,6} \alpha_{ii} P_i +$$

$$+ 2 \Sigma_{j=2,\ldots,6} \alpha_{1j} \left[ \frac{\Sigma_{j=2,\ldots,6} \alpha_{1j} P_j^{1/2} K}{Y_1^{\bar{}} - \alpha_{11} Z - \alpha_1 Z^2 - \Omega} \right] P_j^{1/2} + 2 \Sigma_{i=2,\ldots,6} \Sigma_{j=2,\ldots,6} \alpha_{ij} [P_i P_j]^{1/2}$$

$$+ 2 \alpha_1 \left[ \frac{\Sigma_{j=2,\ldots,6} \alpha_{1j} P_j^{1/2} Z}{Y_1^{\bar{}} - \alpha_{11} Z - \alpha_1 Z^2 - \Omega} \right]^2 Z + 2 \Sigma_{i=2,\ldots,6} \alpha_i P_i Z , \qquad (10)$$

where i does not equal j.

Measures of capacity utilization (CU) assess the current state of the economy and any expansionary or contractionary forces on investment that might exist. The cost-based measure of multiproduct CU for the revenue-maximizing firm with a single quasi-fixed factor is (Segerson and Squires) : $CU_C = W^*/W$. Substituting $W^{*\bar{}}$ gives the quota-constrained $CU_C^{\bar{}}$ : $W_*^{\bar{}}/W$.

The elasticity of $W^{*\bar{}}$ for a change in quota is given by :

$$\frac{\delta \ln W^{*\bar{}}}{\delta \ln Y_1^{\bar{}}} = \left[ \frac{-2 \alpha_{11} q_1^{\bar{}}}{Y_1^{\bar{}} - \alpha_{11} Z - \alpha_1 Z^2 - \Omega} - 2 q_1^{\bar{}} - \frac{4 \alpha_1 Z q_1^{\bar{}}}{Y_1^{\bar{}} - \alpha_{11} Z - \alpha_1 Z^2 - \Omega} \right] \frac{Y_1^{\bar{}}}{W^{*\bar{}}} . \qquad (11)$$

The elasticity of $CU_C^{\bar{}}$ for a change in quota is also given by (11).

## 3. EMPIRICAL RESULTS

Six species or outputs were specified : Dover sole, thornyheads, sablefish, other rockfish, other flatfish, and a residual, all others. Other flatfish, other rockfish, and all others were constructed as Divisia indices of other species using revenue shares as weights. There were 585 observations or fishing trips for 17 vessels, with uneven numbers of trips for each vessel. The quantity landed and revenue by species were recorded each time a vessel landed its catch after a fishing trip. Prices were calculated implicitly. Vessel sizes were from the U.S. Coast Guard. These data were from the PacFIN Research Data Base maintained by the National Marine Fisheries Service.

The supply equations (2) were estimated for unregulated production by vessels less than 75 GRT in 1984. Maximum likelihood estimates for parameters were obtained using Zellner's seemingly unrelated regression iterated to convergence. Each supply equation in (2) was divided by Z after heteroscedasticity of the form discussed by Parks (1970) was discovered, in which the error variance was proportional to $Z^2$. The generalized $R^2$ for the system of equations prior to the heteroscedasticity correction was 0.97. The revenue function was concave in Z at the sample mean and satisfied monotonicity over all observations.

The likelihood ratio tests for the final form of the technology, reported in Table 1, indicate that the technology for conventional levels of significance is not input-output separable and is joint-in-inputs over the entire output set. Hence an aggregate output cannot be formed, and supply management cannot simply regulate aggregate output and must consider the technological and cost tradeoffs among individual species.

The quarterly and area dummy variables are statistically significant. Parameter estimates for the final form of the technology are available upon request.

Unregulated product supply price responsiveness, calculated at the sample mean using equation (6), was highly inelastic (Table 2). Difficulties in locating and harvesting an unseen and spatially dispersed resource, particularly at great depths, and the short production period give this result. Sablefish is a net (Hicksian) substitute in unregulated production to all species except thornyheads, for which it is a net complement. Finally, all own-price elasticities were statistically nonnegative, indicating that the necessary conditions for a well-behaved technology were met.

*3.1 Production quota and supply*

The quota is set at 70 % of the unregulated firm's sample mean production of sablefish. The firm's technology does not inhibit the firm meeting the 30 % reduction in sablefish production, since the positively sloped supply curve supports the quota's virtual price. The industry quota can be met from this perspective.

Production quota reduces the supply responsiveness of the unregulated outputs. The price elasticities under quota, calculated by equation (7) for the 70 % quota, are more inelastic than those prior to regulation (Table 3). Because of the highly inelastic notional supply of the regulated output, reductions in the supply elasticities are sizable, often exceeding 50 %.

In three instances, each involving the all others output, a sign reversal was experienced for the price elasticities : (i) Dover sole supply-all others price ; (ii) other rockfish supply-all others price ; (iii) all others supply-other rockfish price. In each case, net complementary became net substitution. Because these switches do not presently involve species with threatened resource stocks, additional management measures are not required.

The price elasticities of supply under quota can help regulators anticipate the regulated firm's response to changes in regulations and markets. The highly inelastic supply responses under quota indicate that substantial changes in the mix and volume of unregulated outputs are unlikely when market prices change. In addition, a rising sablefish price will not alter the production of other species, and hence not threaten their abundance.

Rising prices of unregulated joint outputs complementary to sablefish, in this case thornyheads, will induce additional sablefish production along the notional sablefish supply curve. Since the expanded sablefish catch is unavoidable, exceeds quota, and cannot be landed on shore, the sablefish production in excess of quota is discarded at sea.[1] Mortality is very high among discarded sablefish, so that the original intention of the quota, enhanced mortality, is in large part defeated.

This pattern of at-sea discards of sablefish is precisely what occurs as growing thornyhead export demand from Japan lifts thornyhead prices. Skippers are forced to weigh the higher returns from increased thornyhead production against the sablefish discards (which may be as much as 16 % ; Pikitch et al. 1988). Since the latter is an external cost which is borne by the entire industry over a period of years (due to the dynamic nature of the resource stock and incomplete property rights), the economic incentive is generally for skippers to maximize short-run private returns.

The quota elasticities for supply of unregulated outputs, calculated by (8), are all quite inelastic (Table 4). The positive elasticity for thornyheads follows from the net complementarity between thornyheads and sablefish. The negative elasticities follow from the net substitutability between sablefish and the other unregulated outputs. Hence, adjustments of the sablefish quota directly alter production of thornyheads, but inversely change production of other species.

If sablefish biomass is further cropped to below the optimum level, the sablefish quota will be correspondingly tightened. Fishing vessels will harvest less of the net complementary species, which will reduce pressure on those resource stocks and tend to enhance their abundance. Because thornyheads already face excessive production, tightening the sablefish quota will also lighten pressures on the thornyhead stock. Hence, an additional thornyhead quota may not be necessary, simplifying the regulations. In contrast, tightening the quota will increase production of sablefish's net substitutes. To date, these other species in this region are not excessively harvested, so that supplemental quotas will not be required.

Regulators are also concerned with the effects of quota upon the individual firm's revenues. The initial change is given by : $R[\bar{q}_1, P^0_{-1} ; Z] - R[P^0_1, P^0_{-1} ; Z]$, where $P_{-1}$ denotes prices exclusive of $P_1$ and the superscript 0 (1) denotes the initial (subsequent) state. $P^0_1 = \bar{q}^0_1$ is used for subsequent quota adjustments. This general formula captures adjustments in the mix and volume of production throughout the firm's product set. The \$1217.38 decline in revenue due to the initial quota was a 17.40 % reduction at the sample mean.

The marginal rent effect of a change in quota is the unit quota rent : $\tau = [P_1 - \bar{q}_1]$, which is \$0.054 for the 70 % quota. At about 32 % of the mean sablefish price, marginal quota adjustments substantially reduce unit rent. The total quota rent evaluated at the sample mean, $\tau \bar{Y}_1$, is \$89.99.

1. In contrast to other industries, control over joint outputs is not absolute because of the commingling of species, incomplete discrimination by the net over product mix, and inability to fully detect and differentiate the different, unseen fish. Carlson (1939) called these joint products technically complementary and noted that they are probably technically complementary over all ranges of outputs ; others (but with greater fixity in output proportions) include cotton and cotton seed and gas and coke.

### *3.2 Production quota and capacity utilization*

Quotas not only regulate the output flow but also alter investment incentives, which could eventually affect industry structure. The significance test of Kulatilaka (1985) indicated that vessels were not in full static equilibrium with their quasi-fixed factor prior to quota. Since $CU_C = 2.54$, these vessels faced incentives to increase vessel size. During recent years, vessels increased the harvest of the deep-water species in ever-deeper waters of the continental slope, progressively migrating further offshore to harvest unexploited stocks in response to sablefish prices growing from developing export markets to Japan. This high-volume, open-access strategy favored larger vessels since vessels did not face full economic costs of production, including the marginal user cost of the resource.

Marginal adjustments in the 70 % sablefish quota only minimally reduce $\tilde{CU}_C$ and $\tilde{W}^*$ since their elasticity with respect to the 70 % quota is very inelastic at 0.12 %. Moreover, the 70 % quota reduces the firm's implicit marginal valuation of its quasi-fixed factor ($\tilde{W}^*$) from \$56.68 prior to regulation to \$55.01 and $CU_C$ drops from 2.54 to 2.47 at the sample mean. $\tilde{W}^*$ and $CU_C$ were only marginally altered by the quota. $\tilde{W}^*$ remains well above the market rental rate and $\tilde{CU}_C$ continues strong investment signals. Hence, the 70 % trip quota and subsequent adjustments do not induce industry exit, satisfying one of the regulatory goals. Nonetheless, this regulatory approach fails from a broader perspective because it does not reverse or even retard the longer-term pressures on the resource and depletion of resource rents from the incomplete property right structure of open access and overcapitalization.

## 4. CONCLUDING REMARKS

This paper used the concept of virtual prices to evaluate the competitive multiproduct firm's supply and investment behavior when faced with a production quota. The properties of the quota-regulated and unregulated supply functions were related, consistently describing behavior under both regimes. The results can be used for designing supply or trade management programs by production quota under joint production.

The effects of imposing a nontradable production quota on sablefish supply to regulate excessive production in an open-access multiproduct fishing industry were assessed. The quota reduces responsiveness of an already highly inelastic system of supply. Rising market prices of sablefish's complement, thornyheads, induces at-sea disposal of sablefish overages. The high mortality thwarts the quota's original intention. Tightening the quota generates spillover harvesting onto most of the other species, reducing their abundance. Because they currently do not face excessive production pressures, supplementary quotas are not necessary to prevent depletion. Imposition of quota and subsequent marginal adjustments substantially impact revenues and quota rents, so that fine-tuning is not warranted unless absolutely necessary. Strong investment signals to the private firm continue in this overcapitalized, open-access fishery.

In sum, the sablefish quota may spread production over the year but the surplus sablefish production disposed at sea largely defeats the quota's purpose by only incompletely slowing short-term resource depletion. Moreover, longer-term pressures from overcapitalization and positive investment incentives under open-access property rights are not substantially altered. An alternative regulatory approach seems warranted.

# The potential Benefits of Individual Transferable Quotas and their Effects on Industry Structure

**Dale Squires** *

National Marine Fisheries Service, Southwest Fisheries Center, P.O. Box 271 La Jolla, California 92038, USA

ABSTRACT

*This paper ex ante analyzes a potential program of individual transferable quotas for two size classes of vessels in a multiproduct common property fishery. The paper finds only moderate total rents and potential efficiency gains from quota trade and explicitly valuing the marginal user cost of the resource. Evaluating the incentives for disinvestment and industry exit after quota exchange indicated potential for a concentrated industry structure with the larger class. Their quota market would potentially be thin, noisy, and noncompetitive, requiring restrictions on their quota transferability and concentration.*

## 1. INTRODUCTION

Individual transferable quotas (ITQs) are increasingly used to regulate common property fishing industries around the world [1]. Under this system, firms are allocated divisible rights to a quantity of an overall quota. Firms trade these quantitative restrictions and adjust production flows, satisfying the overall quota, resource rents are generated, equilibrium market prices for the individual transferable quota develop, and gains from trade are enjoyed. Industries are reorganized on efficiency grounds, with more efficient firms, rather than government, paying a lump sum to higher-cost firms to exchange fishing rights and lower or cease production.

Three issues are of fundamental concern when designing an ITQ program. First, the potential total rents and gains in arbitrage efficiency should be sufficient to warrant an ITQ program. Second, firms are concerned about the expected

* The discussions with, or suggestions of, Harry Campbell, Jon Conrad, Gary Hamer, Larry Jacobson, Jim Kirkley, Anthony Scott, Clem Tisdell, Geoff Waugh, David Wesney and 1990 seminar participants at the Universities of Queensland and Tazmania and Purdue University are gratefully acknowledged. The author is grateful to the Department of Economics, University of Queensland, where this work was completed while the author was a Visiting Lecturer. Pete Leipzig of the Eureka Fisherman's Association identified vessels with high-speed winches. Any errors remain the responsibility of the author. The results are not necessarily those of the National Marine Fisheries Service.

1. See Muse and Schelle (1989) for a review. Scott (1986) notes that ITQs are a right to the resource flow not to the stock itself.

equilibrium market price of a unit quota, which forms a production cost and barrier to entry. Third, regulators are concerned about the expected industry structure (particularly possibilities for quota and industry concentration), competitiveness and thinness of the quota market, and expected rent and efficiency gains. In short, both firms and regulators face considerable uncertainty prior to an ITQ program, and resolution of this uncertainty would eliminate perhaps the chief barrier necessary to gain industry acceptance and cooperation to implement such a program if it is justified.

The purpose of this paper is to *ex ante* analyze a potential ITQ program in a fishery to address the concerns of firms and regulators about the probable consequences. Incentives for disinvestment and industry exit after quota exchange, and subsequent structure of the industry and ITQ market, receive close attention. The prospective gains in economic rent from explicitly valuing the user cost of the resource and arbitrage efficiency created by quota exchange are assessed. The approach builds upon recent advances in the use of virtual prices to model the effects of quantity constraints (Neary and Roberts 1980) and multiproduct capacity utilization to assess firms' investment incentives (Segerson and Squires 1990, 1993).

The approach should be useful for analyzing potential programs for other industries currently or potentially regulated by ITQs. These programs include marketable emission permits for pollution and ITQs for waste management, agriculture, water resources, development rights, oil, and other common property resources. The approach can also shed light on transferable quotas in programs of voluntary export restrictions.

Section 2 develops a generalized ITQ model for use in the empirical analysis. Section 3 gives a background to the fishing industry and introduces the empirical model. Section 4 reports the empirical results and considers the implications for an ITQ program, and the last section contains concluding remarks.

## 2. TRADABLE QUOTA AND THE FIRM

This section examines the problem of applying an ITQ to a revenue-maximizing multiproduct firm facing competitive prices in the absence of prior regulation[2], although the results can be immediately extended to profit-maximization. The problem assumes a certain and static environment and does not allow banking of quota for future use. The quota is assumed to be issued without charge, freely transferable, and denominated in units sufficiently small to contribute to an active and competitive market for quota.

A revenue-maximizing firm facing a binding quota on the first of M outputs, $Y_1$, adjusts both the production levels and quota holdings to maximize revenues. Formally, the Lagrangian is :

$$\max_Y L = \Sigma P_i Y_i + \Theta T(Y ; E) - \tau(Y_1 - y_1) = 0,$$

where $T(Y ; E)$ represents the firm's technology, $\Theta$ and $\tau$ are Lagrange multipliers, Y is a vector of outputs with competitive prices P, E is a vector of quasi-fixed or fixed factors, and $y_1$ is the firm's quota.

The first-order condition with respect to $Y_1$ for an interior solution is : $\delta L/\delta Y_1 = P_1 + \Theta\delta T(Y ; E)/\delta Y_1 - \tau = 0$, where $\delta T(Y ; E)/\delta Y_1 < 0$. $\Theta\delta T(Y ; E)/\delta Y_1$ is the implicit marginal cost of quota. This virtual price, $\phi_1$, is the implicit marginal valuation of an additional unit of quota, the firm's implied opportunity cost of production[3].

The firm's unit quota rent, $\tau = P_1 - \phi_1$, is the difference between the marginal revenue from production, $P_1$, and the virtual price $\phi_1$. $\tau$ is thus the firm's unit producer surplus, and the price which firms are willing to pay for a unit license at that level of quota. A firm m will then demand (supply) quota when $\tau^m > (<) \tau^n$ for another firm n[4]. $P_1$ is constant over all production levels. $\phi_1$ varies with the level of quota held, so that with upward-sloping supply of $Y_1$, quota purchase (sale) monotonically lowers (raises) $\tau$ in the market. The equilibrium market price $\tau^*$ is formed by the Walrasian tatonnement.

2. Exogenous and competitive prices is the small country assumption of international trade. It is appropriate for internationally traded products, in competitive markets, or with very elastic cross-price demand elasticities. This section builds upon Anderson (1988), Maloney and Pearse (1979), and Montgomery (1972).

3. No firm will retain quota in excess of the revenue-maximizing level for Y given a binding and enforced quota and $P_1 > \phi_1$ since revenue is maximized by sale of excess. Hence, $\phi_1$ is evaluated at the quantity of quota held.

4. When markets are thin, price signals are noisy and firms will directly bargain and exchange quota (with high transactions costs and perhaps strategic price behavior), but firms in well-developed auction markets will compare $\tau$ with the existing bid price.

The efficient outcome after competitive exchange of $y_1$ is given by equalizing the net returns from a unit license, $\tau$, across the N heterogeneous firms. Quota exchange amongst firms gives arbitrage efficiency by maximizing producer surplus [5]. The quota rent gained from exchange between firms m and n is :

$$\tau^m - \tau^n = (P_1{}^m - \phi_1{}^m) - (P_1{}^n - \phi_1{}^n),$$

or the producer surplus gain from firm m's greater efficiency, where $\tau^m > \tau^n$. Initial distribution of the quota only affects the distribution of rents, not the efficiency after exchange (Montgomery 1972).

The formal static problem adjusts (through trade) each firm m's initial quota endowment $y_1{}^m$ to maximize returns from quota for each firm and the industry, subject to the constraint that all quotas are used in production. Hence,

$$\max_y L = \Sigma_m \tau^m y_1{}^m + \Gamma(\Sigma_m Y_1{}^m - Q)$$

with N first-order conditions : $\tau^m - \Gamma = 0$, m = 1, ..., N - 1, and $\Sigma_m Y_1{}^m - Q = 0$, where Q is the aggregate quota. The Lagrange multiplier $\Gamma$ is the marginal net benefit of a one unit increase in the overall quota. Rearranging the first N-1 first-order conditions gives $\tau^1 = \tau^2 = ... = \tau^N$. In practice, $\tau^*$ differs between firms by an amount equal to transactions, information, and transport costs[6].

The equilibrium unit rent $\tau^*$ is equivalent to a tax uniform across firms or the competitive market price of the quota initially allocated by auction, except for the distribution of revenue.

A specific tax, $t < \tau$, reduces competitive P and $\tau$ by t.

Over a longer time period, when a firm has time to adjust its quasi-fixed factor E, quota trade may lower the firm's rate of capacity utilization (CU), creating disinvestment incentives[7]. If a firm's implicit marginal valuation of E, i.e. its shadow value, is W*, then the cost-gap multiproduct CU measure for the revenue-maximizing firm is : $CU_C = W^*/W$ (Segerson and Squires 1990, 1993), where W is the market rental rate. $CU_C$ contains information on the implicit costs of divergence from long-run equilibrium. If quota sufficiently reduces W*, CU will also decline. Purchase (sale) of quota will increase (decrease) W * and $CU_C$, and for firms selling quota, $CU_C$ and W* may decline enough to prompt industry exit.

## 3. EMPIRICAL ANALYSIS

### *3.1 Industry background*

The potential benefits and effects of ITQs were studied for an open-access multiproduct trawl fishery off Northern California and Southern Oregon harvesting thornyheads, a fish with an important export market to Japan. This region is the center of the thornyhead fishery on the Pacific coast, and the fishery is concentrated in the deep waters of the continental slope. Overcapitalization of the fleet and growing thornyhead export demand, coupled with the absence of property rights, have placed sufficient pressures upon the biomass to require command-and-control quotas on thornyheads in 1991 for each fishing trip of each vessel.

Quotas without ownership or trade, however, do not tackle the fundamental problem, the absence of property rights. A program of ITQs, in contrast, directly addresses this problem. ITQs also generate arbitrage efficiency and price signals

5. Consumer surplus is constant with competitive price $P_1$ . Assume that any option exercises (allowing for uncertainty) are too small to the total spot quota market volume to affect price.
6. This might inhibit trade, but arbitrage agents would fill part of the gap if the potential market in ITQs is sufficiently large. Thin markets, expectations over property rights and uncertain quota supply raise transactions costs. Lower transactions and information costs can be expected with well-developed markets.
7. Economic efficiency over both the short and long runs has two requirements when controlling an externality : (1) the marginal value of the firm's output must equal marginal cost (both private and external) ; (2) the total value of the firm's output must not be less than total costs (both private and external) (Schulze and d'Arge 1974). The ITQ ensures the satisfaction of the first (short-run) condition for economic efficiency. For the long-run condition, this paper applies recent developments in evaluating firm investment and exit decisions by assessing multiproduct capacity utilization.

formed through market activity. Production and investment decisions are then formed considering all costs. ITQs also allow the most efficient firms to remain in the industry and less efficient firms to lower or cease production induced by a lump sum payment from quota sale.

*3.2 Empirical model*

The industry is comprised of many multiproduct firms. During each fishing trip, vessel operators key production directly to the market, given vessel and resource abundance constraints and fixed competitive prices. Vessels apply inputs to the resource stock for a product flow in a stock-flow technology. Revenue maximization is the objective for the short production period of a fishing trip once a resource stock area has been selected (Kirkley and Strand 1988, Segerson and Squires 1990). Inputs on the vessel are largely fixed because boats are away at sea where inputs cannot be readily altered. Since vessel size or capital stock is fixed at the trip level and largely determines the level of other inputs over this time period of one to four days, the input bundle can be specified as a single, composite input, called effort[8].

The revenue-maximizing production process for each vessel's fishing trip can be modeled by a nonhomothetic generalized Leontief revenue function (Kirkley and Strand) :

$$R[P ; E] = \sum_i \sum_j \alpha_{ij} [P_i P_j]^{1/2} E + \sum_i \alpha_i P_i E^2 + \sum_i \sum_r \alpha_{ir} D_r P_i E + \sum_i \sum_s \alpha_{is} S_s P_i E , \quad (1)$$

where E represents the capital stock or effort, measured by a vessels gross registered tonnage (GRT). The competitive price of product $Y_i$ is $P_i$ and R[P ; E] represents maximum revenue given E and the vector of prices P. $D_r$ is the $r^{th}$ of two home port dummy variables for Brookings and Crescent City and $Q_s$ is the $s^{th}$ of three quarterly dummy variables for winter, spring, and fall. The intercept is used for the port of Eureka in the summer. The area dummy variables account for spatial variations in access to resource stocks, species abundance, and port effects on prices. The quarterly dummy variables account for intertemporal variations in the technological constraints of weather and resource abundance.

Input-compensated supply equations Y*(P ; E) are given by Hotelling's Lemma (McFadden 1978) :

$$\delta R[P ; E]/\delta P_i = Y_i^*(P ; E) = \sum_j \alpha_{ij} [P_j/P_i]^{1/2} E + \alpha_i E^2 + \sum_r \alpha_{ir} D_r E + \sum_s \alpha_{is} Q_s E . \quad (2)$$

Symmetry is imposed by the following econometric restriction : $\alpha_{ij} = \alpha_{ji}$, where i is not equal to j. The Generalized Leontief form automatically imposes linear homogeneity in prices.

**3.2.1 Unit quota rent**

The unit quota rent of a license for $Y_1$, in pounds per trip per vessel, with the Generalized Leontief revenue function is calculated by :

8. Formally, Leontief separability is assumed.

$$\tau = P_1 - \left\{ \frac{E\left[\sum_{2}^{M} \alpha_{1j} P_j^{1/2}\right]}{Y_1 - \alpha_{11} E - \alpha_1 E^2 - \sum_r \alpha_{ir} D_r E - \sum_s \alpha_{is} Q_s E} \right\}^2 , \quad (3)$$

where the term $\{.\}^2$ is the virtual price, $\phi_1$.

### 3.2.2 Market quota price

The equilibrium market quota price after trade, $\tau^*$, can be solved by first finding the trip demand curve from the inverse demand curve (3) and then summing over all firms and trips to give the market demand curve for the annual overall quota. Equating this market demand curve to the perfectly inelastic industry supply of overall quota, Q, gives for $Y_1$ :

$$Q = \sum_k^K \left\{ \sum_j \alpha_{1j} [P_j/(P_1 - \tau)]^{1/2} E + \alpha_{11} E + \alpha_1 E^2 + \sum_r \alpha_{ir} D_r E + \sum_s \alpha_{is} Q_s E \right\} , \quad (4)$$

where j = 2, ..., M, the quota is denominated in one pound units, and K is the observed total number of firm-trips or observations with a binding quota. $\tau^*$ was numerically solved for each value of Q considered. The new "domestic" price vector faced by firms is $\phi_1 = P_1 - \tau^*$. The individual demand curves allow estimation of the equilibrium allocation of quota by vessel and trip.

### 3.2.3 Gain from trade

All thornyhead rents are capitalized in $\tau^*$. Hence $\tau^* Q$ is the full economic rent generated by the resource and the gain in producer surplus compared to open access. $\tau^*$ is the marginal user cost of the unit resource for optimal Q (Maloney and Pearse 1979). $\tau^* Q$ is also the revenue government receives if quota licenses were initially auctioned at a single price or were placed under a uniform tax. Total industry producer surplus under the command-and-control quota equals $\Sigma_k[\tau^k + \frac{1}{2} \varnothing^k] y^k$, where $\Sigma y^k = Q$. The total gain in arbitrage efficiency, or producer surplus, due to exchange at the competitive equilibrium market price, $\tau^*$, is $[\tau^* + \frac{1}{2} \varnothing^*]Q - \Sigma_k[\tau^k + \frac{1}{2} \varnothing^k]y^k$.

### 3.2.4 Data

The data were from the PacFIN Research Data Base maintained by the National Marine Fisheries Service. Landings and revenues were recorded by species at the port of landing after each vessel's fishing trip. The Eureka Fishermen's Marketing Association identified vessels with the high-speed winch required to fish in deep contintental slope waters. Vessel size was from the U.S. Coast Guard and costs were from federal income tax returns.

## 4. EMPIRICAL RESULTS

The model was estimated using data for a year without regulation, 1984. Vessel size affects trip length, hold capacity, weather capabilities, and area and depth fished. These factors, in turn, affect product mix and levels. Hence, the fleet was divided into vessels less than 75 GRT (gross registered tons) and those 75 GRT or more. There were a total of 585 observations or fishing trips on the 16 smaller vessels and 444 observations on the 14 larger vessels, with unequal observations for vessels. Six outputs were specified : Dover sole, thornyheads, sablefish, other flatfish, other rockfish, and a residual category, all others.

The system of input-compensated supply equations, equation (2), was initially estimated by ordinary least squares. Heteroscedasticity was found, in which the error variance was proportional to the squared input level, $E^2$ (Parks, 1971).

Each equation was subsequently divided by E. Maximum likelihood estimates for parameters were obtained using Zellner's seemingly unrelated regression iterated to convergence [9].

The parameter estimates for the smaller vessels are not reported here for brevity, while those for the larger vessels are reported in Segerson and Squires (1993). The generalized $R^2$ for the entire system of equations (Baxter and Cragg 1970) has a value prior to the heteroscedasticity correction of 0.97 for the smaller vessels and 0.99 for the larger vessels. The own- and cross-price input-compensated supply elasticities evaluated at the observed sample mean for the smaller vessels are not reported here for brevity while those for the larger vessels are reported in Segerson and Squires (1993). The own-price elasticities are all nonnegative except for Dover sole for smaller vessels and sablefish for larger vessels, both of which are negative but statistically insignificant. In addition, the revenue function is increasing and concave in E at the sample mean in both cases. Applying the significance test of Kulatilaka (1985) for the shadow value of effort, t-ratios of 0.06 and 4.73 were found at the sample means, indicating that effort was at its full static equilibrium value for large group vessels but that vessels of the small group faced incentives to increase vessel size.

Transferable user rights were initially allocated, without charge, in equal amounts of one pound to each vessel for each trip. This allocation, in effect, gave firms transferable ownership of the 1991 command-and-control trip quota and allowed explicit contrast of the potential gains in economic rent and arbitrage efficiency which would be created by exchange. Firms producing less than permitted by quota were not allowed to retain the quota and banking was not allowed [10]. Inter-group trade was prohibited to spatially distribute production and protect resource stocks.

### *4.1 Distribution of unit quota rent*

The thornyhead unit quota rent prior to exchange, $\tau$, was computed following equation (3) for each trip of each vessel group covering the entire year. Each vessel of the small (large) size class was assigned a quota of 1200 (2100) pounds per trip unless production fell short of this value. A wide range of $\tau$ was observed : 0.0015 to 0.3481 for small vessels and 0.00085 to 0.2488 for large vessels. The standard deviations of $\tau$ were 0.0821 for small vessels and 0.0747 for large vessels.

To assess the distribution of $\tau$ among firms and the factors affecting the size of unit quota rent, $\tau$ was regressed upon an intercept, the area and quarterly dummy variables, vessel size (GRT), and measures of : product-specific economies of scope and scale for thornyheads, multiproduct economies of scale, and $CU_C$. Product-specific economies of scale and scope were for shadow costs and were calculated following Squires and Kirkley (1991). Multiproduct economies of scale were calculated as : $W^* Z/\Sigma_i P_i Y_i$, i.e. total shadow cost divided by total revenue (Laitinen 1980).

The sample was censored and required Tobit analysis, since not all vessels were bound by quota. For the small vessel group, $\tau$ was statistically different by port (Table 1). Seasonal variation in $\tau$ was indicated for both groups. Vessels already facing high CU were also those with economic incentives, through $\tau$, to expand production by quota trade. Vessel size (GRT) reduced $\tau$ for smaller vessels but increased $\tau$ for larger ones. Expanding the short-run overall scale of production lowered $\tau$ for smaller but not larger vessels. Hence, vessels of the smaller group could gain from quota trade and increased production, which would exploit overall scale economies and raise CU. Expanding only thornyhead's scale of production did not affect $\tau$ for either group. Product-specific economies of scope raised $\tau$ for smaller but not larger vessels. In sum, vessels in both groups with high CU had the strongest economic incentives to trade for quota.

9. The functional form is assumed to be exact rather than an approximation, and the errors are from optimization rather than approximation and apply only to the input-compensated supply equations. The problem of zero outputs also arose in a some instances, creating a limited-dependent variable problem, which may cause bias and non-normality of the residuals. The procedure of Lee and Pitt (1987) solves this problem using virtual prices, but is not computationally feasible with the number of variables in this study. A Box-Cox transformation could be used, but was rejected on the grounds that a particular form of non-normal disturbances is assumed prior to transformation. The small value of 0 1 was substituted for zero when necessary. A sensitivity analysis for the large vessel group used values of 0.01 and 0.001 ; the log-likelihood function changed by 0.099 % and 0.246 %, respectively. A few parameter values (particularly those for effort) changed by as much as 5 %, but price elasticities appeared to be robust.

10. Quota allocated when not binding would simply increase Q and K in (4) and lower $\tau^*$, unless smaller amounts were initially allocated. In this case, because the opportunity cost (revenue foregone) of holding quota is zero, $\tau$ is the output price.

*4.2 Market equilibrium quota price*

The equilibrium market prices of quota, $\tau^*$, was solved for each vessel size group :

(i) at the overall sample mean ;
(ii) using mean prices and GRT for four GRT size classes ; and
(iii) over all binding observations[11].

The models were well-behaved at the sample mean, but performance of these second-order approximations deteriorated at some sample observations. These trips were not incorporated in the third approach to calculating $\tau^*$ (otherwise, there was a tendency for equation (4) to slope upwards). Hence, gains in arbitrage efficiency were assessed only for well-behaved binding observations, and some bias was undoubtedly introduced. Values of $\tau^*$ were assessed for a wide range of initial quota allocations.

Fairly close values of $\tau^*$ were found for the three methods with the large vessel group except at the highest quota sizes (Table 2). Values of $\tau^*$ could not be calculated with sample means for large quotas with the small vessel group, since these quotas were not binding. The $\tau^*$ values were similar for the more restrictive quotas.

For both groups, $\tau^*$ was comparatively close to the mean product price per pound of 0.25 dollars, indicating high producer surpluses. The high $\tau^*$ values reflected the steeply sloped supply curves and a high marginal user cost of the resource. In turn, the high marginal user cost relative to price suggests the extent of resource rents potentially gained under rights-based management in comparison to open-access conditions.

Proportional gains in arbitrage efficiency compared to the command-and-control quota were calculated using the binding observations for each group. Fairly similar results (except at large quotas) were found for the large vessel group when using mean values, but model performance deteriorated significantly using means for the four GRT classes of the small vessel group. (These results are available upon request.) The gains in producer surplus, reported in Table 2, were moderate for most of the possible initial allocations of quota for both vessel groups. These moderate gains reflect the relatively small intervessel differences in allocative efficiency.

$\tau^*$ increased for both groups as the quota further restricted production, but the mean quota rent per vessel per trip declined. At high quota levels, only the most efficient vessels (with lower $\phi_1$) traded for quota, while at a lower quota, increasingly inefficient vessels began trade, so that inter-vessel differences in producer surplus narrowed. Hence, proportional gains in arbitrage efficiency tapered off with tighter quota, although total potential gains in producer surplus rose.

Total rent for the small vessel group, beyond the largest quotas, declined at a fairly slow rate as quota tightened (Table 2). Market quota demand was thus somewhat elastic over most of its range. Total rent for large vessels first rose rapidly then continued to rise but at a very slow rate as the quota declined when calculated using all binding observations. When calculated using mean values, total rent slowly declined. Hence, market demand for the large group was either inelastic but almost unit elastic or slightly elastic. In sum, for both vessel groups and for all methods of calculation, market demand was not strongly inelastic, reflecting the large number of substitute species in production.

A broad range of overall quotas is thus available to maximize the fishery's static optimum rent. This result, however, must be tempered by considerations of resource conservation, i.e. the dynamics of the resource stock. Because calculations of optimum stock size generally have a wide confidence band, relatively conservative stock estimates can be used without a large opportunity cost of rent foregone. This conservative strategy protects the resource stock and insulates the industry against abrupt and large reductions in the overall quota if new stock assessments show a sudden population decline or that previous resource assessments were in error.

11. Certain regularity conditions (particularly convexity) are often violated over large sample regions with a flexible functional form (FFF). These violations can be for reasons other than failure to satisfy the model's behavioral assumptions. For example, Wales (1977) showed that estimates of a FFF may violate regularity conditions even if the data came from a well-behaved technology. Functional forms that *a priori* satisfy all regularity conditions sacrifice flexibility and impose restrictive assumptions (homogeneity and separability). Imposing convexity, either globally or over a region (see Diewert and Wales (1987) and Roller (1990)), is convenient for simulation work and is consistent with economic theory, but also obscures economic responses. Eliminating troublesome parameters can also give convexity but imposes unknown structure and bias upon the model and reduces flexibility. Eliminating observations causing violations also creates biased results. Evaluating results at a point more likely to be well-behaved, such as the sample mean or point of approximation, is useful, but masks results for individual firms. In short, all methods obscure economic relations. This paper blends an analysis of the well-behaved individual observations and analyses at sample means with extensive knowledge of the industry and data to spark insights into the most probable economic relationships.

Total rents, for each of the three methods of calculation, were relatively small for each vessel group. These limited total rents reflected the small size of the industry and an ITQ program regulating a single species in a multispecies fishery. The rents could be smaller than the regulatory costs of planning, implementing, monitoring, and enforcing an ITQ program for thornyheads.

Extending the ITQ program to additional species would expand the resource rents, giving a more favorable benefit-cost ratio. Expansion, however, would face the marked inability of vessels to make substantive changes in the mix and volume of their optimal product mix. In this fishery, at least, the technology and shadow cost structure prohibit such adjustments (Squires and Kirkley, 1991). Hence, as a response to microregulation of the individual multiple products, vessels discard excess production, causing unnecessary mortality and countering many of the expected beneifits of an ITQ program.

A variety of remedies have been proposed (see Schelle and Muse and Copes 1986 for reviews), but they all rely upon some combination of complex trading or taxation schemes, large and well-functioning markets with minimal transactions and information costs, or fairly obedient firms. These proposed solutions all fly in the face of one of the chief lessons learned from over a decade of deregulation in a wide range of industries : the limits to complex microregulation.

### *4.3 Quota and capacity utilization*

ITQs induce less efficient firms to lower or even cease production. Firms disinvest and exit the industry if, after exchange, $\tau^*$ and the amount of quota retained after trade lower $\phi_1$, and hence the firm's implicit marginal valuation of effort (W*), by a sufficient amount below its market rental rate (W). Equivalently, the equilibrium allocation of quota might sufficiently reduce the firm's CU to induce disinvestment and industry exit. That is, an ITQ program creating property rights over the resource flow forces firms to explicitly confront the user cost of the resource, $\tau^*$, and reevaluate investment decisions in light of full costs.

The changes in CUs were evaluated for both $\tau$ and $\tau^*$ for each vessel's trip to assess these possibilities. Calculations used all of the binding (and well behaved) observations. Quota prior to exchange reduced CUs by a sizable amount in all cases[12]. After $\tau^*$ was formed through exchange, CUs climbed for firms buying quota and further dropped for firms selling quota.

Mean W* and CU per vessel per trip for the small vessel group usually became negative with quotas before exchange but climbed to positive values after trade. Because of the high initial CU values prior to quota, CUs after exchange declined for only a few vessels by such a visible amount as to suggest disinvestment and industry exit. The sizable CU declines were for some of the larger vessels in the small group, as noted from the Tobit analysis.

Most vessels in the larger vessel group, in contrast, experienced a marked decline in the mean CU per vessel per trip after quota exchange. The shadow price of effort, W*, and hence CU, frequently became negative, giving strong signals for disinvestment or exit from the fleet, each vessel receiving a lump sum payment $\tau^* y_1$. These vessels tended to be the smaller ones in the larger vessel group, as noted from the Tobit analysis.

Several vessels in the larger group with strong disinvestment incentives also had cost incentives (lower $\phi_1$) to trade for quota, but had low CU even prior to quota. Purchase of quota raised $\phi_1$ and W*, but it was insufficient to give positive values of W* and $CU_C$ because the quota seriously lowered CU for these vessels.

In short, tradable property rights in this common property fishery created a uniform price signal $\tau^*$ and forced firms to explicitly account for the resource's user cost and restructure accordingly. Prior to the ITQ program, vessels mined the resource stock in ever-deeper waters of the continental slope, progressively migrating farther offshore to harvest unexploited stocks. Because this high-volume, open-access production strategy favored larger-sized vessels, vessels of the smaller group had high rates of CU and economic incentives to expand effort. In contrast, open-access effort of larger vessels was in full static equilibrium. The ITQ program, however, confronted firms with full social costs. This, in turn, lowered the firm's implicit marginal valuation of effort (W*) and CU. Smaller-sized vessels in the small vessel group remained, but only a few of larger-sized vessels of the larger vessel group were suited to produce at the socially optimal rate. $\tau^*$ is sufficiently small to not pose a prohibitive entry barrier. Finally, this prospective analysis suggests that ITQs can provide considerable impetus to reduced capitalization in a fishery.

12. Primarily due to the steep thornyhead supply curve, so that even a moderate quota seriously lowered $\phi_1$, and hence W * and CU.

*4.4 Concentration of quota*

Exchange of a quota may be unwelcome if it facilitates the concentration of quota in the hands of a limited number of producers (Scott 1986). The full equilibrium cost and technological determinants of multiproduct industry structure, prior to ITQs, did not favor extensive horizontal or vertical integration of vessels into multivessel firms (Squires and Kirkley). However, ITQs would potentially generate such sharp disinvestment and exit incentives for so many firms in the larger vessel group as to suggest that quota will become concentrated in the hands of the few remaining firms. Hence, for the larger vessel group, the quota market risks becoming thin, noisy, and hampered by noncompetitive forces, potentially requiring limits to quota transfer and concentration.

## 5. CONCLUDING REMARKS

This paper evaluated a prospective program of individual transferable quotas for two vessel groups in a common property fishery. Explicitly accounting for the user cost of the common property resource by the ITQs created strong disinvestment and exit signals for the large vessel group, so that a concentrated industry structure was possibly favored. Their quota market is potentially thin, noisy, and noncompetitive, and may require limits to transferability and concentration of quota. The small vessel group, however, appeared to have close to the appropriate vessel numbers and sizes with ITQs.

The quota created strong disinvestment and exit incentives for a surprisingly large number of firms, even for those purchasing quota, by weakening the firm's implicit marginal valuation of capital and lowering capacity utilization. That is, a tradable quota remains a quota, and not just inefficient firms may face serious disinvestment incentives, but also a number of more efficient firms with low initial economic capacity utilization.

Finally, in contrast to the current command-and-control quota, explicitly valuing the user cost of the resource and allowing quota trade created economic rents and moderate gains in arbitrage efficiency. In contrast to open-access, resource rent can be enjoyed under rights-based management.

These gains were nonetheless limited, calling into question the efficacy of an ITQ program as a rent generator for a single species in a multispecies fishery. Extending ITQ coverage to other species encounters the problem of microregulation of multiple products when the technology and cost structure preclude sizable changes in the mix and volume of products without at-sea disposal. Complex trading rules or taxation schemes are a possible solution, but simple and robust regulations seem to have the greatest chance of success.

The primary regulatory alternative of license limitation with a vigorous vessel buy-back program has fallen out of fashing in favor of ITQs. Yet, given the limits to microregulation of joint products (Kirkley and Strand, Squires and Kirkley 1991, Squires 1987), this alternative should reexamined in this light. A supplementary ITQ might then offer protection to the most threatened species and provide a strong complementary impetus to vessel reductions.

ABSTRACT

*The estimation of productivity and efficiency provides a useful tool to evaluate the economic consequences of the regulation policy on the fishing enterprises. The purpose of this paper is to examine some measures of productivity and efficiency of the fleets. The theoretical background of this methodology is the multi-input and multi-output firm behaviour. We use the "production-frontier" function definition to measure input or output inefficiency through a cross-section data analysis. We apply this methodology to the artisanal fleet of Boulogne-sur-mer which is the first French landing port. We have constructed a data base from the daily log-book statistics and we have selected a homogenous sample of 74 trawlers. This example shows how the adoption of different criteria can lead to diverse classifications of the ships.*

## 1. INTRODUCTION

The exploitation of the North Sea fisheries by the French Fishing Fleet, was marked by the relative decline in the importance of 'industrial' vessels and the growing influence of small scale fishing enterprises (Lemoine, 1988).

Because of the risks of over-exploitation of the principal species of the North Sea the European Community took an array of measures aimed at limiting catches. These measures include the total banning of herring fishing during the end of the 70's, a number of temporary suspension of fishing for certain species and various regulations concerning the capturing equipment used by trawlers, mainly the mesh size.

* This study has been prepared with IFREMER. The authors wish to acknowledge the helpful comments of Alain Laurec (EEC-DG XIV) and Alain Maucorps (IFREMER).

In parallel the Community introduced the MAGP's in 1988 in an attempt to reduce permanently the capacity of the fishinng fleets both in terms of tonnage and horse power. A critical and comprehensive survey of these measures can be found in Weber (1990).

The set of these regulatory instruments employed by the Community correspond to their theoretical counterparts cited in the theoretical bio-economic models (Clark, 1985). The usefuleness and limits of such measures have been the objects of several studies (Meuriot, 1987).

An important problem which arises by the application of such instruments of fisheries management is their impact on the profitability of the fishing enterprise. It was noticed that the fleet of the 16-25m trawlers has shown a strong tendency to invest in capital equipement during the mid 1980's as the value of their landings increased. Was such move justified in the presence of this regulatory apparatus ?

The analysis of the different profitability ratios and their indebtness which was established by the examination the accounting information from a sample of 27 among 88 vessels between 1985 and 1989, has revealed that their profitability has shown some decline as their gross margins were squeezed and at the same time their debt burden increased regularly.

Such trends make the analysis of the productivity and efficacy along with the study of their rate of capacity utilisation to be essential in order to appreciate the economic situation of these fishing enterprises and measure the impact of the regulatory measures on their functions.

## 2. PRODUCTIVITY AND EFFICIENCY : SOME THEORETICAL CONSIDERATIONS

Productivity is the relationship between production and inputs, normally capital and labour. It is a measure used frequently to quantify the economic performance of the firm. However, productivity is as it requires the calculation of several ratios between each of the inputs to output. Furthermore such measure does not indicate whether the enterprise is using its utilised inputs optimally.

In an effort to construct the appropriate indices which can measure the degree of 'efficiency', the concept of the 'frontier production functions' has been developed. The literature in this area is quite extensive and we site the work of Tulkens (1988) as a more recent survey of the theoretical concepts involved and Simar anf Deprins (1988) for the relevant econometric applications.

The frontier production function defines, for any given quantity of inputs the maximal output possible, or for any given level of output the minimal quantities of inputs required. Therefore the enterprise will be considered efficient if the appropriately constructed index of its performance, places it on the frontier. Enterprises which do not belong to the frontier are said to be inefficient. If we were to observe an increase in output for the same level of inputs, that is a shift of the frontier, we then talk of technical progress.

The construction of such an index of efficiency requires the definition of a absolute scale. To avoid this problem we will measure the efficiency of each enterprise in terms of the others and utilise a measure of relative efficiency. Thus an enterprise will be judged inefficient and dominated in output if one were to find that other firms produce the same of more output using less of the same levels of inputs. A convinient starting point will the construction of the simpler index of relative efficiency as the ratio between the output of the enterprise and the maximal productions previously encountered.

## 3. MEASURES OF PRODUCTIVITY OF THE TRAWLERS IN BOULOGNE SUR MER

In the light of the previous discussion we set to examine the performance of the 'small scale' fishing trawlers. Our sample consists of a number of fishing units whose log-books were obtained (Allard, 1991). The log books contain information of captures per species, number of days fishing and the number of hours fishing during. In Boulogne there are in excess of 250 fishing vessels which land their catch, but here we concen trate exclusivelly on boats between 16-25, for two main reasons :

(i) they constituted a fishing fleet having access to the the same fishing technology, thus they can be said to technologically homogeneous and

(ii) the accounting information available can be statistically analysed in the context of the concepts used in fisheries economics. The totality of their landings are auctionned a set up which allows to verify the data on captures and the information on time spend fishing can be translated to a measure of fishing effort which is of importance in the literature.

We have constructed a data base of boats using the motor's power and time fishing as factors of production and turnover as a mesure of output. The utilisation of time fishing as a factor of production has eliminated some of the boats from the sample, as they did not report it. We have finally retained 62 boats from the 88 available.

The calculation of the fishing time productivity (Y/TIME) and the motor power productivity (Y/HP) show the median measures of 263 FF/hour and 1610 FF/hour respectively. There was however a great deal of dispersion between the most and least productive boats as the following table (Table 1)

Therefore the calculation of the boat's characteristics following that their productivity is above or below the median does not always allow for the same values for these criteria and consequently the same fishing units, as the classification in Table 2.

Here we remark that the boats which are most productive in terms of motor power (Y/HP>Median) have the same characteristics than the most productive ships in terms of Y/Time. However, the boats with the lowest values of Y/HP have a fishing time which is lower, by 3.5pc, and have turnovers which are higher, by 4 pc in comparison to those whose Y/TIME productivity is low : the ships with the lowest productivity in terms of Y/Time or in terms of Y/HP are not the same.

## 4. MEASURES OF EFFICIENCY OF THE TRAWLERS IN BOULOGNE SUR MER

The application of the concept of efficiency, as defined in the second paragraph, allows us to define 20 boats, considering the inputs and output and classify them as 'efficient'[1] Figure 1 presents the production function frontier. The 'efficient' ships are on the envelop of the production function.

The identification of these vessels as the most productive in terms of Y/TIME and the Y/HP criteria, makes evident that are only one half of the boats common to the intersection of the set of these boats which are deemed efficient in terms of the Y/HP and as thus classified using Y/TIME as a measure of productivity. In consequence the characterisation of the fishing units interms of turnover, fishing time and engive power is quite different following the criretion of efficiency used, as it can be seen of Table 3.

This example shows that how the adoption of different criteria can lead to diverse classifications. In effect the vessels which are more productive in terms of Y/TIME have obviously lower average value for fishing time. Thus the advantages of the use of the criterion of efficiency which combines both inputs are been made clear. Finally, this example points out some undesirable effects of fisheries management tools : the reduction of the global horse power of the fishing fleet does not involve an homothetic decrease of the catches.

1. We have used a criteria in terms of output efficiency : a fishing unit is dominated in output terms if an other boat has both an higher turnover and input factors which are lower or equal. In this case the fishing unit is 'non efficient'. The output efficiency index is defined as the ratio of the turnover divided by the turnover of the closest efficient ship.

# Setting Total Allowable Catches based on Market Conditions : Economics of Atlantic Herring Roe Production

**Robert Nowak**

Department of Fisheries and Oceans, Scotia-Fundy Region, P.O. Box 550 Halifax, Nova Scotia, B3J 2S7, Canada

ABSTRACT

*For many years fishery biologists, economists and resource managers have struggled to define some "optimal" criterion to set the amount of maximum harvest or total allowable catch (TAC). Many reference points have been suggested. Biologists used objective biological criteria to establish maximum sustainable yields (MSY). Economists have proposed the maximum economic yield (MEY) concept which maximizes a stream of net revenues. Meanwhile, pragmatic fishery managers have used a combination of political, biological and economic factors to determine TACs to address a multitude of conflicting "socioeconomic" objectives (Optimal Sustainable Yields).*

*In recent years, a new term has appeared : a "market-determined" TAC. Specifically, the Atlantic Canada herring industry has argued that the abundance of herring, the dominance of the Japanese herring roe market by Canadian exports and limited alternative markets for other herring products constitute required conditions to introduce a market TAC.*

*This paper presents a framework for evaluation of the market-determined TAC concept based on the Scotia-Fundy (4WX) herring purse seine fishery. Although the term implies some relationship between the amount of fish allowed to be caught/sold and market conditions, it is not an ambiguous concept. At best, it could be defined as an initiative that prevents oversupplying market segments currently occupied by Canadian products. The paper describes the program's potential design, its effectiveness and distributional consequences. It is shown that a strategy of limiting catches might be the wrong strategy to pursue for the 4WX herring fishermen. A simple quantity-dependent model is used to estimate the price elasticity of final demand for flavoured herring roe products. These policy implications, however, may be misleading given a speculative and non-competitive nature of the Japanese market. Thus, the paper considers other methods of market manipulation particularly, the possibility of "designing" a different market structure in order to ensure a more favourable outcome. The inherent instability and difficulty in distribution of potential gains also disqualifies this approach.*

## 1. INTRODUCTION

Market considerations have recently been suggested as a potential reference point in determining the amount of maximum herring harvest. Specifically, the Atlantic Canada herring industry has argued that the abundance of herring, the dominance of the Japanese herring roe market by Canadian exports and limited alternate markets for other herring products constitute required conditions to introduce a "market-determined" total allowable catch (TAC). Although the term implies some relationship between the amount of fish allowed to be caught or sold and market conditions, it is not an unambiguous concept. At best, it could be vaguely defined as an initiative that "prevents oversupplying market segments currently occupied by Canadian products" (Kirby, 1982, p.289).

This paper consists of four main sections. First, a short history of the herring roe market is presented. Second, various reference points used to establish TACs are discussed. Third, a simple demand model is used to estimate the price elasticity of demand for flavoured herring roe products. Finally, it is shown that a strategy of limiting herring catches in Atlantic Canada might be the wrong strategy to pursue for reasons other than those implied by the elasticity estimates.

## 2. AN OVERVIEW OF THE HERRING ROE FISHERY

Consumption of herring roe (kazunoko) is deeply rooted in Japanese tradition. For decades it has played an integral part of Christmas, New Year and wedding celebrations in Japan. The name itself (prolific eggs as opposed to herring eggs) confirms kazunoko's special position in the Japanese culture. Japan is also the principal market for kazunoko in the world.

Japanese fishing fleets used to satisfy most of the domestic demand for herring. Subsequently Japanese catches gradually declined, but herring import quotas effectively prevented a market penetration by foreign producers. In 1972 trade restrictions were relaxed and for the next few years Chinese fleets supplied most of the Japanese herring market with the residual being supplied by Canadian British Columbia catches. Subsequent depletion of Chinese herring stocks allowed the B.C. production to become the dominant supplier (Alley, 1982).

In Japan, herring roe products fall into two distinct groups. The traditional product is salted roe (shio kazunoko). It is consumed mostly during Christmas holidays or given as a year-end gift. Pacific herring is predominantly used for this product. It is estimated that less than 20 % of Atlantic herring roe is salted (less than 10 % of Atlantic Canada herring roe). Consumption of salted roe has reached a maturity stage with static consumption patterns (Anderson et al, 1989). The other class of products, flavoured herring roe (ajitsuke kazunoko), was developed in the 1980s. It is believed that this range of products was developed to utilize herring roe unsuitable for salted roe production. Flavours include soya sauce, brandy, hot peppers and wine. Over 90 % of Atlantic Canada herring roe exports goes into production of flavoured roe. Unlike salted herring roe, these products are promoted as snacks for consumption throughout the year.

The emergence of a market for flavoured herring roe has been rapid. Atlantic Canada herring roe production increased from 400 tonnes in 1983 to almost 8,000 tonnes in 1990. Two Canadian regions export roe to Japan : the Atlantic part of the province of Nova Scotia (Scotia-Fundy Region) and the Gulf of St. Lawrence (Gulf Region). In Scotia-Fundy most herring is caught using purse seines. Fishing for herring roe has become the most important activity for about 40 purse seine vessels. In 1988, about 70 % of all purse seine landings were for roe extraction. In the Gulf Region, fishing for herring has also become an increasingly important income supplement to cod, crab, and lobster for about 600 fishermen employed on 200-300 boats. In Gulf, herring for roe extraction are caught using gillnets.

While Canadian herring fishermen and processors are becoming more dependent on herring roe sales, there have been continuous reports of "unsatisfactory" pricing and grading methods by Japanese buyers. The Atlantic Canada industry believes that the Japanese use discriminatory (monopsonistic) pricing to their advantage. For example, Japanese buyers have been reported to use information on the number of weeks the plant workers needed to qualify for Unemployment Insurance in price and volume negotiations. These negotiations frequently continue for weeks after the roe has been shipped to Japan. Although no specific proposals have been posited, some segments of the Atlantic Canada herring roe industry believe the same marketing arrangement is necessary to counteract this unfavourable market structure. It has been suggested that a market-determined total allowable catch (ie., limited roe sales) would strengthen the weak bargaining position of Canadian sellers and increase their revenues.

## 3. TOTAL ALLOWABLE CATCH

For many years fishery biologists, economists and resource managers have attempted to define some criterion to set the amount of maximum harvest or total allowable catch. Many reference points have been suggested. Originally, biologists used objective biological criteria such as maximum sustainable yields (MSY). Subsequently, this reference point was declared *not sustainable*, not operational and thus unacceptable (Larkin, 1977). The concept of maximum sustainable yield is the simplest biological management objective that aims at the maximum harvest (in perpetuity) without altering the stock level. The concept is based on the assumption that the exploitable population of each stock has an optimum size which could be maintained if the annual catches are equal to the annual natural increases in the stock size.

The concept relies crucially on the assumption that catches are the only factor influencing fish populations ; it completely ignores natural fluctuations in stock abundance. Given the presence of stock fluctuations, it is clear that constant-yield policies cannot be optimal and/or sustained (Clark, 1985). In addition to natural stock fluctuations, the TACs based on MSY do not prevent further stock declines because of incomplete catch statistics, overfishing, and lags in scientific advice. Furthermore, the MSY concept completely ignores economic costs of exploitation of the resource while the single most important objective of fishing is earning money and not fish removal per se. Fishermen operate in the world of fluctuating fish stocks and are confronted with changing prices, exchange rates, interest rates, fuel costs and shifting tastes. To account for these factors, economists have proposed the maximum economic yield (MEY) concept.

The static MEY point represents the point where economic rent is maximized (without intertemporal considerations and fishermen are price takers). This is the point where the difference between revenues and costs of fishing is largest. In economic jargon, this happens where incremental revenues (marginal revenue) obtained through adding a small amount of input costs (marginal cost) are just equal. This useful reference point, however, is rarely observed in practice as most fisheries employ redundant capital and labour relative to the available supply of fish.

The employment of redundant capital and labour is well-documented in economic literature. Fishermen collectively are not economic profit maximizers (and fish at effort levels beyond MEY) not because of irrationality, but due to the undesirable aggregate outcome of their individual actions. In case of unrestricted entry fisheries, the new entrants are not worried about their effect on other fishermen. They are concerned with their own revenues. As long as average revenue is greater than marginal cost new fishermen will be attracted to the fishery until the open-access equilibrium is reached. In case of restricted (limited) entry fisheries, fishing effort (cost of fishing) increases through more "intensive" fishing practices by the existing boats (input stuffing). This is usually accomplished by the use of more powerful, bigger vessels, more efficient fish finding technology or any other efficiency increasing method allowed by fishing authorities.

In an intertemporal setting, the dynamic MEY maximizes a stream of net revenues. This concept, however, may be burdened by the difficulty in choosing the appropriate social discount rate and time horizon. The choice of a discount rate is crucial as the most desirable point of economic exploitation may fall anywhere between the static maximum economic yield and open-access points depending on society's time preference (Cunningham and Whitmarsh, 1981).

The significance of the magnitude of discount rate in determination of optimal TACs has been established. In fact, Clark (1973) showed that given no preference between present and future income (a zero discount rate), static and dynamic MEY points coincide. In case of an infinite discount rate (when future income has no value), the dynamic MEY is equivalent to the open-access point. Subsequent research has, however, complicated this intuitively simple solution. For example, Farzin (1984) and Hannesson (1987) illustrated, for exhaustible and renewable resources respectively, that the discount rate has an ambiguous effect on the optimal rate of resource extraction. This happens because a higher discount rate may increase extraction-harvesting costs (by raising opportunity cost of capital), thus forcing a lower level of exploitation. This effect may or may not outweigh an incentive to catch more the higher the discount rate (ie., the time preference effect).

Both MSY and MEY concepts serve as useful reference points but have been criticized for pursuing single objectives. There exist, however, other reference points which attempt to trade off various biological, economic and ecological factors. For example, the $F_{0.1}$ fishing mortality strategy, officially adopted as the management criterion by Canada in 1977, recognized explicitly the need for stock rebuilding. The $F_{0.1}$ strategy is based on the concept of the marginal yield from fish stocks (Gulland, 1968). The $F_{0.1}$ fishing mortality criterion is defined to be that fishing mortality which is derived from application of "a marginal yield equal to one-tenth of the original catch per unit of effort in the very lightly exploited fishery" (Gulland and Boerema, 1972).

The theory of $F_{0.1}$ predicts larger biomass over time consistent with the task of stock rebuilding. Other benefits of this strategy include larger fish and more year classes in spawning biomass. Biologists claim that the $F_{0.1}$ fishing mortality

may use less than two-thirds of the effort maximizing yield (Canada, 1988). The $F_{0.1}$ is also supposed to embrace practical concerns. The 10 % "safety buffer" (although completely arbitrary) addresses uncertainty. However, the $F_{0.1}$ strategy may be outdated and its usefulness questionable under the current exclusive 200-mile fishing jurisdiction (Canada, 1987). In addition, biological and economic premises on which this approach is based may also require a closer examination (Lane, 1989).

The choice of an appropriate reference point implicitly reflects the return maximizing strategy by fishing authorities. For example, the MEY emphasizes cost minimization while the $F_{0.1}$ recommends more and bigger fish (higher revenues). Naturally, a strategy suggesting higher per unit fish prices (ie., market TAC) belongs in the same class of reference points. In addition, while the $F_{0.1}$ strategy entails efficiency, equity, biology and employment trade-offs, the market-TAC approach would also involve a similar compromise[1].

## 4. MARKET DEMAND FOR HERRING ROE PRODUCTS IN JAPAN

Typically, common property characteristics and particularly competition for the fixed supply of fish among fishermen causes the desired catch to exceed the level established by fishing authorities. In economic terms, this occurs because each fisherman faces a perfectly elastic (horizontal) demand curve. As a price taker he cannot influence prices. Thus, increases in his revenues can only be obtained through increased catches while a port market is most likely to absorb available supply at prevailing prices.

In contrast, the market final demand curve is usually downward sloping. This implies higher prices can be obtained by lowering quantities (and vice versa). Accordingly, sellers could act as price makers, as opposed to price takers facing a horizontal demand curve, provided that they are "dominant" suppliers (between 1980 and 1990 Canadian exports of frozen herring roe had on average 85 % of the frozen herring roe market share in Japan). The greater the market share, the higher the chances of successful price setting by sellers. This market mechanism is, in fact, well recognized. For example, a fishermen's union spokesman was recently quoted : "Japan, the main buyer of herring roe, had a surplus from last year and is controlling prices." He also added that "if a limit was set to 2,000 tonnes in the Bay of Chaleur and 2,000 in Fundy, supply would be limited and the Japanese buyers would no longer be in a position to keep prices down."[2]

The quote, of course, implicitly assumes that reduction in quantities sold will be outweighed by increased prices resulting in higher revenues. In fact, a ratio of a percentage change in quantity over a percentage change in price (or price elasticity of demand) measures the magnitude of such changes. If the demand is inelastic (less than one), a change in price causes a less than proportionate change in quantity demanded. Thus, lower quantities lead to higher revenues when an industry operates on the inelastic portion of the market demand curve. If the demand is elastic (greater than one), a change in price causes a more than proportionate change in quantity. Thus, total revenue rises when price falls and falls when price rises.

Although there have been no market demand estimates for flavoured (or frozen) herring roe, the elasticity for salted herring roe has been estimated to be inelastic or close to one (Table 1). Of particular importance is the fact that the calculated estimates vary depending on the season or market segment studied. The estimates of Anderson et al (1989) along with economic theory may assist in predicting the price elasticity of demand for flavoured herring roe. For example, the more the possible uses of a commodity the more elastic the demand for a commodity is expected to be, and if the commodity has close substitutes, the more elastic it should be. In general, luxury goods are price elastic, while necessities are price inelastic. Demand is also more elastic in the long run. Because flavoured herring roe has many substitutes (it is consumed as snacks competing with other snacks) and cannot be classified as a necessity, one would expect it to be price elastic.

Table 2 illustrates a rough test to indicate the relationship between frozen herring roe prices and quantities. It also measures approximate price elasticities evaluated at a Canadian plant level, ceteris paribus. In Scotia-Fundy, the data

1. In general, the presence of economic, biological and social compromises inevitably leads to a concept of Maximum Social Yield (Anderson, 1977). In essence, sometimes, it may be necessary to move away from economic and biological paradigms in order to satisfy other objectives. For example, promotion of fishery underemployment in economically disadvantaged areas with few employment alternatives might be such a different objective.
2. "Fishermen looking for herring limit", *The Telegraph-Journal*, August 23, 1991.

indicate a negative relationship between quantity sold and price received for frozen herring roe in 1983-1990. On three occasions, however, an increase (decrease) in quantities sold coincided with an increase (decrease) in corresponding prices. In contrast, in the Gulf Region, this unorthodox relationship seems to have been prevalent for all, but two years. It is clear that this method based on ex-plant Canadian data is neither conclusive nor rigorous (ie., an identification problem) with respect to the hypothesized relationship between quantities traded and prices and the estimate of price elasticity. Thus, a formal demand model has been formulated and estimated.

## 5. THE MODEL

The model tested in this paper is of the form :

$$Q = aP^b P^c Y^d$$

All coefficients were determined from the following log-log, static equation (ignoring dummy variables, time subscripts and error terms) :

$$\ln Q = a + b \ln P + c \ln P_s + d \ln Y$$

where :

| | |
|---|---|
| Q = quantity demanded | a = intercept |
| P = own price | b = price elasticity of demand |
| $P_s$ = price of substitutes | c = cross price elasticity |
| Y = income | d = income elasticity of demand |

and the expected signs of coefficients are $b < 0$, $c > 0$, $d > 0$

Wholesale Sapporo auction monthly price data for years 1984-1990 were used as a proxy for retail data (the Sapporo market is considered to be the price setter for flavoured herring roe in other Japanese markets). Average monthly prices were available therefore differences in quality and size could not be taken into account. The quantity variables were calculated as traded auction quantities prorated by Japanese domestic consumption. The income data were given by a per capita Gross National Expenditure. A substitute price index was chosen arbitrarily and proxied by food price index. All nominal variables were deflated by the Japanese Consumer Price Index. Some equations employed dummy variables to distinguish between the November/December demand and the rest of the year demand (auction data strongly suggested a structural break in November). Data were obtained from a variety of sources : OECD Main Economic Indicators ; Economic Statistics Annual, 1990, The Bank of Japan ; Japanese Fisheries Market Report, August 1991, Department of External Affairs ; Bill Atkinson's News Report (Issue 410) ; and Annual Report of Sapporo Central Wholesale Market.

Ten different equations were tested (Table 3). The first five equations had "quantity-dependent" specifications. In this case economic theory suggests prices set by the "Walrasian auctioneer" which together with income and substitute effects determines quantities demanded. The other five equations were of "price-dependent" type. Price-dependent specifications conveniently allow for the supply of fish to be exogenously determined (variations in supply cause variations in prices not vice versa). It is worthwhile to note that fishery products demand studies have created a debate among economists with respect to proper approaches, functional forms, specifications and included variables (see Nash and Bell, 1969 ; DeVoretz, 1987 ; Schrank et al., 1988).

The quantity-dependent specifications (equations 1-5) performed fairly well. Equation 4 supplied the best fit :

$$\begin{matrix} \text{Ln } Q_t = & 22.39 & - 2.43D_t & + (0.2D_t & - 1.09)\ln P_t & + 3.55 \ln Y_t \\ & (3.25) & (-0.49) & (0.29) & (-1.63) & (4.13) \end{matrix}$$

where :

t-statistics in parentheses

$Q_t$ = per capita quantity demanded

$P_t$ = deflated price

$Y_t$ = per capita real income

$D_t$ = binary (dummy) variable

$D_t$ = 0 for November and December, $D_t$ = 1 otherwise

Given the logarithmic functional form, coefficients represent respective, constant elasticities. (The linear specifications did not produce satisfactory results and are not reported). The income coefficient was statistically significant and positive (greater than unity) indicating that flavoured herring roe is a normal and luxury good. (3.55 is the value of income elasticity of demand). The price variable had the expected sign. Price elasticity of demand (for November and December) was -1.09 ; and price elasticity for the months January through October was -0.89. The hypothesis of unitary price elasticity of demand in November/December could not be rejected at a 1 per cent level of significance. The price elasticity of -1.0 for January-October was statistically significant at a 1 per cent level.

The price-dependent specifications (equations 6-10) did not perform satisfactorily. The key quantity variable displayed the wrong sign in most cases and was not statistically significant. All equations were corrected for autocorrelation (AR1). High coefficients of determination and statistically non-significant t-statistics suggested presence of multicollinearity. The estimated elasticities of both income and own price were extremely high. It is interesting to note that these results confirm other fish demand studies where results are sensitive to the choice of the functional forms (linear or logarithmic) and the choice of the dependent variable.

The results of equation 4 indicate that the demand for flavoured herring roe is unit elastic at the auction level. This has interesting implications. First, it indicates that sellers of flavoured roe obtain maximum revenues. Second, assuming a competitive distribution chain, revenues of Canadian fishermen and processors are also maximized. Adjustments in fishing effort will not produce higher revenues and there exist no double maxima revenue curve (Anderson, 1973). Third, if employment considerations are important, Canadian sellers should not attempt to reduce the quantities offered. This means that contraction of output destined for the Japanese herring roe market could be the wrong strategy to pursue. On the contrary, expanding frozen herring roe sales to Japan would increase domestic employment. In addition, the estimated coefficients are for "total" flavoured herring roe. The demand for herring roe of Atlantic Canada origin would be more elastic (due to the possibility of substituting roe from other countries or even British Columbia). The more elastic the demand, the greater will be gains from expanded sales.

The major shortcoming of the model proposed here is lack of explicit consideration given to inventories. Specifically, a consistent carry-over of inventory could imply a non-competitive market structure which should be modelled appropriately. In addition, the impact of exchange rates should be taken into account. In many cases exchange rate fluctuations play a more important role than price changes in revenue determination.

## 6. MARKET STRUCTURE : THEORETICAL AND EMPIRICAL EVIDENCE

If sellers were to act as a monopoly, the profit maximizing strategy would require setting output (or prices) at the point where marginal costs equal marginal revenues (price > marginal revenue). Because monopolist must operate on the positive portion of the marginal revenue curve (on the elastic portion of market demand curve), the profit maximizing price would be higher than that maximizing total revenue. Thus herring roe sellers would benefit if they could act as a monopoly (conditional on the position of average cost curve)[3].

However, establishing a monopoly may be costly and/or unsuccessful. This section evaluates pragmatic and qualitative factors which may disqualify the market TAC approach in this fishery. Moreover, because some economists believe that

3. Maximization of profits and consumer surplus would result in a greater social benefit than maximizing profits alone. Because all herring roe is sold abroad thus foreigners would bear reductions in consumer surplus and deadweight losses.

"to date the empirical results in the area of fish products demand have been too diverse to permit strong policy recommendations to be based on them" (Schrank et al., 1988), empirical evidence is provided to illustrate some typical responses of fishing industry to government-imposed market structures.

Market structure plays an extremely important role in determining prices and output produced. On the one hand, a monopolist is able to set a higher than purely competitive price and reduce his output, thus increasing his overall profits. This particular market structure raises distributional issues : a redirection of income from consumers to producers and deadweight losses. On the other hand, a bilateral monopoly provides an indeterminate outcome : the equilibrium in such a market cannot be determined by the traditional economic tools of demand and supply (Fellner, 1947). Economic analysis can only define the range within which the price will eventually be settled. The precise level of the price (and output) will depend on the bargaining power, skills and other strategies of the participants.

Table 4 illustrates a selective survey of theoretical literature describing various market structures in fisheries, but provides no unambiguous basis for favouring one market structure over the other. In essence, socially efficient outcomes are determinate only under specific conditions. Moreover, provided all Atlantic Canada herring roe is exported, a socially efficient solution would not be sought by a profit-maximizing monopolist or export cartel.

According to economic theory, the main condition for a successful export cartel is that the elasticity of demand for imports must be low in the relevant price range. This condition can be extended into two others : (1) the elasticity of supply for the "cartelized" good must be low and (2) the cartel must control a large share of the world market for the commodity.

The previous section has shown that demand for frozen herring roe imports is unit elastic. (Demand for *Canadian* exports, as discussed above, could be even more elastic.) Conditions (1) and (2) above are also violated confirming the reasonableness of the previously calculated estimates. First, effective barriers to entry into the Japanese herring roe market do not exist. In fact, the number of countries exporting roe to Japan tripled in the 1980s. Canadian roe exports have been increasing, but at a lower rate than competitors, particularly the Europeans (Anderson et al, 1987).

Second, although Atlantic Canada exports satisfy between 75 and 97 per cent of the Japanese demand, herring roe products have numerous substitutes not only among other roes. As previously mentioned flavoured herring roe competes in the "snack" market. Moreover, the product substitution takes place not only at the retail level, but also at the intermediate input level (ie., lower quality Pacific roe is used in production of flavoured roe and the highest quality frozen roe is salted for the Christmas gift market). In conclusion, the market-TAC approach for Atlantic Canada exports of frozen herring roe may reduce total revenues even in the short-run.

There exists other evidence suggesting that export cartels rarely achieve maximum joint profits. Cartels are unstable because individual firms do not have identical costs ; market demand must be correctly estimated for the price demanded to be the monopoly price ; each individual firm has a strong incentive to present low-cost figures during cartel negotiations and cheat on their subsequent output. Finally market conditions usually change faster than the cartel's ability to negotiate new agreements.

Moreover, different skills and motivations, different levels of profitability, different attitudes toward risk-taking, the long tradition of competitive spirit among fishermen and technological progress are variables influencing the behaviour of fishermen. The imposition of a central planner would certainly introduce a conflict among private firms (of unequal capabilities and differing interests), in addition to the bureaucratic rigidities, reduced innovation and entrepreneurial drive[4]. Specifically, distribution of relative gains and losses between domestic fishermen and processors would be difficult to accomplish (Kirby, 1982)[5].

These economic predictions have been tested empirically. For example, White and Mace (1988) show that cooperative arrangements among fishermen seldom persist. In Scotia-Fundy, a herring fishermen's co-op, created with the assistance

4. Hayek (1989) argues that competition, not cooperation is the only way to discover what resources we have and which uses of these resources would add most to its total product. In short, it is not possible to design an order in which participants interact through some sort of central authority. Any such a deliberate arrangement would deny itself information (prices) necessary for its profit maximizing approach.
5. "It has been suggested that Canadian processors could take advantage of their large share of some market segments to extract higher prices by restricting the flow of product to a given market and charging customers higher prices. In practice, however, the absence of a practical way of restricting the flow of Canadian products to a particular market or buyer, while compensating those firms whose products would be diverted to less profitable markets or left in the sea, largely eliminates the possibility of attempting to exercise this kind of market power" (Kirby, p.294).

of government in the 1970s, broke down fairly quickly. Despite the cartel collectively bargaining over the price of herring with buyers and allocating catch quotas among its members, individual arrangements between fishermen and buyers undermined the cartel's activities. Low cost producers (highliners) felt their individual quotas were not as high as they were capable of catching. In economic terms, foregone rents to intramarginal fishermen were greater than the total gains from this cooperative arrangement.

In Norway a sales cooperative created to maintain order in the salmon marketplace recently filed for bankruptcy (Seafood Leader, 1992). Of particular interest were reports of circumvention (or outright cheating) of minimum export prices by farmers and exporters of fresh salmon. The natural tendency to overproduce is shown by the "mountains" of frozen salmon in the cooperative's freezers.

If neither cheating nor expensive accumulation of unsold products, destroy cartels division of perceived gains may. For example, Chinese authorities set farmed shrimp prices which when disregarded lead to standoffs between shrimp farmers and buyers. As a result processors handle most of the harvest in a short time leading to poor quality product and lost revenues for exporters. This price setting system is largely ineffective : "The Chinese will tell farmers how much they can grow and what prices they can charge, and they will tell processors how much they can charge. But someone forgot to tell the outside world how much they should pay" (Seafood Leader, 1991).

Finally, international trade theory predicts that an export restriction would cause a shortage of herring roe in Japan creating an additional profit margin between price and costs. This profit would most likely accrue to Canada (depending on the method used to limit exports). In other words, while an export restricting strategy may be beneficial to Canada as a supplier of the large world market share, the Japanese as the principal world demander of that commodity may retaliate through tariffs capturing that profit margin. The final outcome of such herring roe trade war may not be beneficial to Canada. It should be noted that the Japanese used tariff revenues to compensate herring fishermen after the domestic herring stocks collapsed in the 1960s (Alley, 1982).

## 7. CONCLUSIONS

1. Market TAC constitutes a valid concept in the family of reference points used to determine total allowable catches.

2. Preliminary estimates suggest that price elasticity of final demand for flavoured herring roe is unit elastic. This result does not satisfy the necessary condition for implementation of market TAC for the Atlantic Canada herring roe fishery.

3. Theoretical considerations show no conclusive evidence that the existing "regulated competitive" structure is inferior to any other regulated market structure. This is further supported by other countries' experience with minimum export prices or cartel-like arrangements. Furthermore the costs of setting up such institutions and enforcing the optimal economic behaviour would likely be prohibitive.

5. The success of implementing a market TAc is doubtful because of the existence of many international herring roe suppliers and substitutes for herring roe.

6. The "market" TAC approach can work well if its main function is distributional and not profit maximization. For example, allowable catches of capelin in Atlantic Canada are limited to approximate Japanese market demand. The capelin management plan is designed to prevent gear conflicts and allow all licensed capelin fishermen to have fair access to the resource. (Capelin migrate northward and it is possible to satisfy market requirements before all fishermen have had a chance to fish it.)

ABSTRACT

*A variety of regulations have been imposed on marine fisheries, often with results that were neither intended nor anticipated. Most of the literature on fisheries regulation looks at the implications for the size of the optimal biomass. In this paper, we focus instead on the individual fisherman and analyze the conditions under which the fisherman will engage in illegal fishing. We consider two forms of regulation : output controls and input controls. We find there is a difference in the behavior of the fisherman depending on the type of regulation imposed. We also examine the management implication for the two regulatory regimes under the assumption that enforcement is costly. This allows us to examine what happens to the optimal management if there are differing enforcement costs for each form of regulation.*

## 1. INTRODUCTION

A variety of regulations have been implemented on marine fisheries, often with results that were neither intended nor anticipated. These regulations arise from biological, political, economic and social concerns. Regardless of motivation, regulations are often changed because new vessels appear that are equipped to exploit loopholes in the regulations or to evade them. The idea of individual transferable quotas (ITQs), a reform designed to improve economic efficiency, has arisen at least in part because other policies have failed. Copes (1986) has argued that ITQs may yet prove subject to similar regulatory problems, and several other authors at least entertain this possibility (Pearse, 1988 ; Scott, 1988 ; Smith, 1985). Furthermore, several authors argue that the failure of regulations to control fishing effort shows not enough work on the microeconomics of fisheries has been done (Anderson, 1989 ; Anderson and Lee, 1986 ; Wilen, 1985).

* This research was supported by the Social Sciences and Humanities Research Council of Canada under grant 410-87-0329, the Natural Sciences and Engineering Research Council under grant A6745, and the Department of Fisheries and Oceans' Science Subvention Program. Helpful comments were received from A.D. Scott and W.R.S. Sutherland. The typing efforts of Monique Comeau and Heather Lennox are also greatly appreciated.

The microeconomic analysis of fisheries has proceeded on two fronts. The first approach assumes that fishermen will attempt to influence regulatory policy in a self-interested fashion. Thus Karpoff (1987) shows that restrictions on tonnage or length, mandated use of obsolete gear, and seasonal or area closures, though ostensibly intended to control fishing effort, can be used to secure distributional shares for groups that are at a competitive disadvantage. Similarly, Dupont (1990) argues regulation of British Columbia's salmon fisheries provides implicit quotas to types of gear that are inefficient. Thus, rent-seeking behavior on the part of different groups of fishermen offers one explanation as to why inefficient regimes persist.

The second body of literature examines the response of self-interested fishermen to regulations that are not perfectly enforced. If enforcement is costly, it is not optimal to ensure complete compliance. Evasion will occur on the basis of marginal returns to individual decisionmakers (Becker, 1968 ; Stigler, 1971). Efforts to control externalities in marine fisheries present such a situation. Optimal enforcement policies have been analyzed by Sutinen and Anderson (1985), who adapt Becker's (1968) framework. Sutinen and Gauvin (1989) examine evasive behaviour in the lobster fishery of Massachusetts. New Zealand recently implemented individual transferable quotas on its fisheries with careful attention to enforcement. Detailed records of fishing activity must be kept and are subject to audit. Violations are treated as commercial fraud (Clark et al., 1988).

This work notwithstanding, questions concerning the design and enforcement of regulations remain. Assuming that enforcement is costly, are there circumstances when restrictions of inputs are preferable to control of output or vice versa? In this paper, we compare the effects of input restrictions on the behavior of individual fishermen with the effects of output controls.

In the next section, we derive a short-run profit-maximizing model of an individual fisherman operating in an environment of no regulation and compare this with the case of imperfect input regulation and imperfect output regulation. In the third section, we examine the implications of the models for management policy.

## 2. A MODEL OF FISHERMEN'S BEHAVIOR

Consider the situation of a limited entry fishery, in which the number of fishermen, the size of each fisherman's vessel and the initial biomass available in the fishery are taken as given. We assume that there are two variable inputs, x and x′. These variable inputs can be thought of as bundles of inputs, with some inputs the same in each bundle. For example, x could be a given configuration of electronic gear, labor, fuel, and nets of a certain mesh size. The bundle x′ would then be a bundle with the same electronic gear, fuel, and labor, but with nets of a different mesh size. The fisherman then decides how much of each bundle he will use, according to the usual profit-maximizing rules.

The harvest level, $h_j$, of the jth fisherman is given by the short-run production function

$$h_j = h_j(x_j, x_j' ; K_j, B) \tag{1}$$

where $x_j$ and $x_j'$ are the amounts of the variable input bundles; $K_j$ is the capital stock, for example, measured by the size of the boat, and B is the biomass of fish available. Each fisherman is assumed to be a price-taker in the market for the variable inputs and pays w and w′ for them, respectively.

### *2.1 No regulation*

Each fisherman is assumed to maximize short-run restricted profits by choosing the optimal combination of $x_j$ and $x_j'$. In the case where there is no regulation of the fishery, the fisherman's single-year optimization problem is given by

$$\max_{x_j,\, x_j'} \{ph_j (x_j, x_j' ; K_j, B) - wx_j - w'x_j' : h_j \in T\} \tag{2}$$

where p is the unit price of output, assumed parametric to the fisherman, and T represents the technology set. Solution of this optimization problem results in the standard condition that the fisherman uses each variable input up to the point where the value of the marginal product equals the marginal cost of the factor (in this case, the parametric w and w') :

$$ph_x = w \tag{3a}$$

$$ph_{x'} = w' \tag{3b}$$

where $h_x = \partial h_j/\partial x_j$ and so forth.

The optimal harvest level for the fisherman, $h^*_j$, is then determined from the production function by evaluating it at the optimal levels of $x_j$ and $x'_j$ chosen.

$$h_j^* = h_j(x_j^*, x_j^{*'}; K_j, B) \tag{4}$$

where $x^*_j$ and $x^{*'}_j$ are the optimal level of inputs determined from equations (3).

### 2.2 *Regulation with imperfect enforcement*

Now assume the fisherman faces a regulatory constraint on harvesting activities, either in terms of inputs (e.g., days of fishing, mesh size) or output (e.g., catch quotas), but that enforcement is imperfect. In the case of output controls, let $h_j$ be the fisherman's allowable quota. Illegal harvest in the case of output control is then defined as $h'_j = h_j - \bar{h}_j$ for $h_j > \bar{h}_j$[1]. In the case of input regulations, we define $x'_j$ as the illegal bundle of inputs (for example, involving illegal mesh size or fishing in a closed area or season) and $x_j$ as the legal bundle of inputs.

We assume the fisherman can fish illegally, but faces a probability, $\theta_j$, of being caught and convicted if he does so. This probability is a positive function both of the level of enforcement and the amount of illegal fishing that occurs. We assume that, if caught, the fisherman is convicted and assessed a fine, $F_j$, thus increasing the costs of fishing. We assume the fishermen are risk-neutral, and do not engage in rent-seeking behavior ; that is, they do not incur variable costs specifically to have the regulations changed. Finally, we assume the fishermen do not incur variable costs to avoid detection of any illegal activities[2].

We specify the probability and fine functions as follows. The probability of fisherman j being caught fishing illegally is given by

$$\theta_j = \theta(h'_j, E) \tag{5a}$$

$$\theta_{j'} \geq 0, \quad \theta_E > 0, \quad \theta_j \equiv 0 \quad \text{if } h_j < \bar{h}_j$$

$$\theta_j = \theta(x'_j, E) \tag{5b}$$

$$\theta_{x'} \geq 0, \quad \theta_E > 0, \quad \theta_j \equiv 0 \quad \text{if } x_j < 0$$

where E is some measure of the level of enforcement, $h'_j$ and $x'_j$ are defined above, and $\theta$ is a suitable function whose range is [0, 1]. The probability of being caught in both cases depends positively on the level of enforcement and on the level of illegal activity, where illegal activity is defined according to whether input controls or output controls are imposed.

The fine paid by the jth fisherman if caught is also determined by the amount of illegal activity that occurred, and is limited by the assets of the fisherman, as proxied by the capital stock K.

$$F_j = F(h'_j ; K_j)$$

$$F_{h'} > 0, \quad F_j \equiv 0 \quad \text{if} \quad h_j < \bar{h}_j \tag{6a}$$

1. In the absence of transferable quotas, it is likely $h'_j \geq 0$ ; that is $h_j \geq \bar{h}$. Our analysis, however, holds for $h_j < \bar{h}$. We assume the quotas are not transferable and that they have been allocated on the basis of past activity. While there is an extensive literature on the optimal allocation of quotas, we do not address the question here, so as to focus the discussion on the impact of input and output regulations on fishermen's behavior.
2. See Milliman (1986) and Anderson (1987) for models that incorporate the cost of avoidance activities.

$$F_j = F(x_j' ; K_j)$$
$$F_{x'} > 0 , \quad F_j \equiv 0 \quad \text{if} \quad x_j' = 0 \tag{6b}$$

The expected value of the fine for the jth fisherman is $\theta_j F_j$. An ideal enforcement policy would set the expected value of the fine equal to the social opportunity cost of the illegal behavior at the margin (Posner, 1977 ; Becker, 1968, among others). Although in theory this could result in a very large fine, in practice, it is reasonable to assume that the fine does not exceed the assets of the fisherman, as represented by $K_j$.

### 2.2.1 Imperfect enforcement with output regulations

With a given individual quota of $\bar{h}_j$ and some probability of being caught if the catch is greater than $\bar{h}_j$, the fisherman's optimization problem in equation (2) becomes

$$\max_{x_j, x_j'} \{ph_j(x_j, x_j' ; K_j, B_t) - wx_j - w' x_j' - \theta_j F_j\} \tag{7}$$

where both $x_j$ and $x'_j$ are legal inputs and where the expected fine for illegal fishing is an additional cost of operations, penalizing that portion of the fisherman's harvest above the allowed catch.

The first-order conditions yield the profit-maximizing solution

$$[p - (\theta_{h'} F + \theta F_{h'})] h_x \leq w \tag{8a}$$

with equality if $h' > 0$

$$[p - (\theta_{h'} F + \theta F_{h'})] h_{x'} \leq w' \tag{8b}$$

with equality if $h' > 0$

Equations (8) are similar to equations (3), except that the effective unit price for fish received by the fisherman has been reduced by the additional opportunity cost of being fined if fishing occurs beyond the legal quota. This opportunity cost is the marginal expected fine, which is equal to the increase in probability of being caught, for a given level of fine ($\theta_{h'} F$) plus the increase in the size of the fine for a given probability of being caught ($\theta F_{h'}$). The fisherman will thus exceed his prescribed quota as long as the marginal value of the catch net of the expected fine exceeds marginal factor cost. In the absence of illegal fishing ($h_j \leq \bar{h}_j$), $\theta = F \equiv 0$, and equations (8) collapse to equations (3).

### 2.2.2 Imperfect enforcement with input regulations

What happens when the regulations are on inputs? The fisherman now faces the choice of fishing illegally by using illegal inputs. The optimization problem is the same as in equation (7), except $x_j'$ is now illegal input. We again are concerned not with the optimal level of input regulations, but rather with the fisherman's behavior in the face of a given set of input regulations. The first-order conditions are similar to equations (8) except $\theta$ and F are now assumed to be functions of x′.

$$ph_x = w \tag{9a}$$

$$[ph_{x'} - (\theta_{x'} F + \theta F_{x'})] \leq w' \tag{9b}$$

with equality if $x' > 0$

Equation (9a) is the standard first-order condition when there is no regulation. In equation (9b), the second term on the lefthand side is again the marginal expected fine. Equation (9b) differs from equations (8) in that the marginal expected fine is not multiplied by the marginal product of x′. This is because in equation (8), where output is regulated, the penalty

feeds back indirectly to the variable input through the production relationship; hence the extra term $h_x$·. In equation (9b), where input is directly regulated, the effect of the penalty is more straightforward. But again the interpretation is that illegal fishing will occur if the marginal value of the catch net of the expected fine exceeds the marginal factor cost.

## 3. MANAGEMENT IMPLICATIONS

In this section, we address the intertemporal optimization problem faced by the fishery manager, who is assumed to be charged with the task of maximizing resource rents. We consider two possible scenarios:

(i) a situation of perfect and costless enforcement, undertaken for comparative purposes, in which an omnipotent manager is able to control completely the inputs used by each fisherman to obtain a "first-best" solution, and

(ii) a more realistic case in which the only means available to regulate the fishery is through the choice of an enforcement level E (assuming a fixed definition of what constitutes illegal fishing activity).

In both cases, the resource manager is assumed to maximize the discounted present value of net economic rents, given the population dynamics of the biomass. These are specified as follows :

$$dB/dt = g(B) - H \tag{10}$$

where g(B) represents the natural growth rate of the biomass and the total harvest is $H = \Sigma h_j = \Sigma f_j(x_j, x_j', K_j ; B)$.

### *3.1 Perfect and Costless Enforcement*

In this case, the values of each fisherman's inputs $x_j$ and $x_j'$ are determined not by the behavioral models discussed above, but rather by a global optimization in which $x_j$ and $x_j'$ are treated as decision variables for the manager rather than for the fisherman. Furthermore, there are no costs of enforcement since no enforcement is necessary. The manager's objective can be written simply as :

$$\text{Max} \int_{x_j,\, x_j'} e^{-\delta t}(pH - C)\, dt \tag{11}$$

where $H = \Sigma h_j$ as above, $C = \Sigma(wx_j + w' x_j')$ represents the total variable cost of fishing for the industry as a whole, and the optimization is subject to the dynamics of equation (10). Applying the Maximum Principle, and assuming for simplicity that an internal solution determines each fisherman's input levels, the optimal equilibrium conditions are as follows :

$$g(B) = H \tag{12}$$

$$g'(B) + \left[\frac{p - \mu}{\mu}\right] H_B = \delta \tag{13}$$

$$(p - \mu)(\partial h_j/\partial x_j) = w \quad \text{and} \quad (p - \mu)(\partial h_j/\partial x_j') = w' \qquad j = 1, \ldots, N \tag{14}$$

where $\mu$ is the shadow value of the fish stock. These 2N + 2 equations determine the 2N controls $\{x_j, x_j' ; j = 1, \ldots, N\}$, the state variable B and the shadow value $\mu$. Note that in equation (13), the lefthand side represents the marginal productivity of the stock, g'(B), adjusted by the "marginal stock effect" (Clark and Munro, 1975), which measures the effects of changes in the biomass on harvest levels and costs. This is equated to society's rate of discount $\delta$, representing the opportunity cost to society of the resource stock.

### *3.2 Imperfect and Costly Enforcement*

We turn now to the case of intertemporal optimization in which the fishery manager can control only the level of enforcement effort over time, while decisions concerning desired inputs are left to the individual fisherman. The results

of the behavioral modelling presented earlier indicate that each fisherman j will select a pair of inputs $x_j$ and $x_j'$ to optimize profits, given specified biomass B, enforcement activity E, capital stock $K_j$, and individual production function $h_j = f_j(x_j, x_j', K_j\ B)$. From here on, the resulting inputs desired by fisherman j will be written as $x_j = x_j(E, B)$ and $x'_j = x'_j(E, B)$, suppressing the dependence on $K_j$ for simplicity. Note that these behavioral response functions differ for the cases of input and of output regulation ; in both cases, however, they combine to produce a harvest level $h_j$. As above we denote the total harvest and the total variable cost by $H = \sum h_j$ and $C = \sum(wx_j + w' x_j')$, respectively.

Given this instantaneous behavioral response by fisherman to enforcement effort E(t) at any time t, the intertemporal optimization problem can be written :

$$\underset{E}{\text{Max}} \int e^{-\delta t}(pH - C - c_E)\, dt \tag{15}$$

where now the fishery manager has only the enforcement activity E as a regulatory instrument. Total societal costs now include the cost of the enforcement effort, $c_E = c_E(E)$, which is assumed to increase with E, so that $c'_E(E) > 0$. While in reality the precise nature of the enforcement activity will differ under input versus output control, we assume here that E is measured in comparable physical units, and represents a "pre-optimized" mix of enforcement options.

This optimization problem is again subject to the stock dynamics in equation (10). However, the harvest H and total costs C now involve input *functions* $x_j(E, B)$ and $x_j'(E, B)$, which are behavioral responses to enforcement activity and biomass levels, rather than being decision variables to be chosen by the fishery manager :

$$H = \sum f_j(x_j(E, B), x_j'(E, B), K_j ; B) = H(E, B)$$

$$C = \sum [wx_j(E, B) + w' x_j'(E, B)] = C(E, B).$$

Using the Maximum Principle, we find that the following equations, combined with either (8) or (9) in the cases of output or input controls, respectively, completely determine the optimal equilibrium :

$$g(B) = H \tag{16}$$

$$g'(B) + \frac{\left(\frac{dH}{dB}\right)\left(\frac{dC}{dE} + c_E'\right) - \left(\frac{dH}{dE}\right)\left(\frac{dC}{dB}\right)}{p\left(\frac{dH}{dE}\right) - \frac{dC}{dE} - c_E'} = \delta \tag{17}$$

As above, the lefthand side of (17) represents the marginal productivity of the stock, g'(B), adjusted by the "marginal stock effect". It is equated to the opportunity cost of the resource stock δ. In this case, the marginal stock effect can be written explicitly in terms of the total derivatives dH/dE, dC/dE, dH/dB and dC/dB. The latter terms can be expressed explicitly in terms of the production functions and the response functions $x_j(E, B)$, $x'_j(EB)$. That is $dH/dE = \sum(h_x x_E + h_x x'_E)$, $dC/dE = \sum(wx_E + w' x'_E)$, and so on. In particular, it should be noted that the total derivative, dH/dB, in equation (17) is quite different from the partial derivative $H_B = \partial H/\partial B$ in equation (13), since in equation (17) the total harvest H depends on the biomass not only directly, but also through the response functions $x_j$ (E, B) and $x_j'(E, B)$.

### *3.3 Interpretation*

The next logical step in this analysis might be a comparison of imperfect regulation using output and input controls, as given by equations (16) and (17) combined with equations (8) or (9), with the optimal first-best equilibrium in the case of "perfect costless" enforcement, as indicated in equations (12)-(14). The goal would be to determine the relative merits of input versus output controls, and the incentive gap produced by these methods of imperfect regulation.

However, the results of the above analysis demand a quite different interpretation. We find that in the present relatively complex multi-dimensional model, the structure of the sole-owner optimum in equations (12)-(14) is not comparable with the case of imperfect regulation. Indeed, the very different behavioral response functions obtained under output and input controls makes a direct comparison of these methods impossible (except under drastic simplifying assumptions).

This result should not be surprising, since the present model reflects, first, the complexity of the real-world situation, in which input and output controls must be "fine-tuned" to specific circumstances, rather than being viewed as artificial constructs, and, second, the nature of behavioral models, which focus on attempts to mimic actual fishermen behavior, however complex, rather than on the use of simple assumptions to produce tractable analyses.

While not surprising, the findings here are nevertheless of considerable importance in policy analysis. They point to the impossibility of determining *theoretically* the relative merits of the various regulatory instruments, and the resulting critical need for more empirical analysis to compare such instruments in particular cases.

## 4. CONCLUSIONS

This paper has presented and analysed a unified model of illegal fishermen behavior under imperfect enforcement of input or output regulations. As in past studies, it has been shown that fishermen will fish illegally (exceeding their quotas or using illegal gear) if the marginal value of the catch, net of the expected marginal fine, exceeds the marginal factor cost.

We have also examined the optimal societal equilibrium in the case of imperfect enforcement and in the sole-owner case of perfect costless enforcement. In each case, we obtained a clear depiction of the optimal equilibrium as a set of simultaneous equations. However, these equations cannot be directly compared, a fact which highlights the complexity of real-world regulatory environments, the impossibility of determining *theoretically* the relative merits of regulatory instruments, and the corresponding need to determine the merits of regulatory options in specific cases, by applying the present results in detailed empirical studies[3].

3 Our results differ from the standard results (e.g., Clark (1976)) both because we specify the harvesting and cost functions as explicit functions of the biomass and because we do not assume linear homogeneity of the cost function.

# Fixed or Variable Catch Quotas with Irreversible Investments

**Stein Ivar Steinshamm**

Institute of Fisheries Economics, Norwegian School of Economics and Business Administration

ABSTRACT

*The objective of this paper is to compare two different management strategies for a long-lived fish stock with stochastic recruitment, namely constant catch quotas (TACs) versus variable catch quotas based on a constant level of fishing effort. The analysis is based on a simple aggregated biomass model. The first part of the paper considers some theoretical aspects of the problem with irreversible investments, and identifies expected a priori outcomes from the model compared to a model where investments are reversible.*

*In the second part Monte Carlo simulations are used to quantify the differences in profitability between the strategies. One of the main conclusions of the paper is that the profitability of fixed catch quotas is highly dependent on the degree of investment irreversibility such that the difference in profitability between the strategies becomes greater, the more irreversible investments are.*

## 1. INTRODUCTION

Optimal schemes for fisheries management based on mathematical programming models may be hard to carry out in practice. It is difficult to make an exact and complete specification of the objective function and the side constraints in such models. The more detailed this formulation is, the harder it is to solve the optimization problem. Even when a solution is found, the parameter estimates used in the model are often subject to uncertainty or may be error prone in other ways. The resulting optimum is often a complex strategy with a high degree of pulse fishing. This is the reason why fisheries managers are often inclined to resort to so-called reference points or rules of thumb in managing real fisheries. Advanced mathematical models are often only used for theoretical and educational purposes.

Examples of reference points used in fisheries are $F_{max}$, $F_{0.1}$, constant escapement, constant effort (CE) or constant catch (CC) quotas[1]. In this paper it will be concentrated on the last two alternatives.

Constant effort and constant catch have been shown to perform about equally well with respect to economic return under a variety of circumstances (Steinshamn, 1991). Constant catch, however, has had a reputation of increasing risk and instability in the fish population. This is certainly true if the catch is adjusted to maximize yield biomass but it needs not be the case if the catch is kept at a moderate level. A constant catch adjusted to maximize the net economic return will in many cases imply a moderate rate of harvest. It has been shown that an optimally adjusted constant catch in many respects compares to the $F_{0.1}$ strategy (Murawski & Idoine, 1989).

If the question about irreversible investments and fixed capital is taken into account, things may change. It is the purpose of this paper to compare the economic performaces of constant effort and constant catch under such circumstances. It is also interesting to see how this depends on the degree of irreversibility. These comparisons will be performed both with an aggregate biomass model and a multi-cohort model. First of all a description of the model and a reference to the case without irreversible investments will be given.

## 2. THE MODEL

The model is an aggregate biomass model where the dynamics is given by

$$B_{t+1} = s\xi_t + w_t \tag{1}$$

$B_t$ is biomass, $\xi_t$ is escapement and $w_t$ is recruitment, all at time t, and s is the survival parameter. In the basic model the following production function is assumed :

$$u_t = E_t Bt \tag{2}$$

where $E_t$ is the effort level at time t. The objective function to maximize is given by

$$V = \sum_{t=0}^{T} \alpha^t \pi(u_t, B_t) \tag{3}$$

where $\pi$ is the net revenue function and $\alpha$ is the discount factor $(1+r)^{-1}$, r is the discount rate. The net revenue function can be written

$$\pi(u_t, B_t) = pu_t - C(u_t, B_t) \tag{4}$$

where p is the price per unit harvest and C() is the cost function. The cost function is defined as

$$C(u_t, B_t) = cE(u_t, B_t) \tag{5}$$

where c is the cost per unit effort, and effort is here written as a function of u and B. Given Eq. (2) above, this function is simply $E_t = u_t/B_t$ The net revenue function can therefore be rewritten

$$\pi(u_t, B_t) = (p - c / B_t)u_t \tag{6a}$$

or

1. $F_{max}$ is the fishing mortality maximizing yield per recruit and $F_{0.1}$ is the fishing mortality corresponding to the point on the yield per recruit curve that has a slope which is 10% of the slope through the origin.

$$\pi(E_t,B_t) = (pB_t - c)E_t \tag{6b}$$

$\delta\pi/\delta B > 0$ whereas $\delta\pi/\delta u$ and $\delta\pi/\delta E$ are only greater than zero if $(p - c/B) > 0$, that is when the biomass level is higher than the level that results in an open access fishery.

To start with the simplest possible model as a reference, assume constant recruitment, $wt = w\forall t$ and no discounting, $r = 0$ (i.e. = 1). The objective is first to derive the optimal equilibrium by maximizing

$$V = \sum_{t=0}^{\alpha} \pi(u_t,B_t) \tag{7}$$

It is obvious that with a constant recruitment the optimal equilibrium will imply both constant effort and constant catch. In other words, the three optimal solutions, unconstrained optimum, optimal constant effort and optimal constant catch will coincide. However, with zero discounting it is clear from Eq. (7) that the objective function will not converge, and it will therefore be replaced by the long-term average

$$V = \frac{1}{T} \sum_{t=0}^{T} \pi(u_t,B_t) \tag{8}$$

see e.g. Clark (1976 : p.386). This has to be maximized subject to the dynamic constraint, Eq. (1), and subject to $B_t - u_t \geq \zeta_{min}$ for all t where $\xi_{min}$ is the minimum escapement level required to secure future recruitment. Assuming that an equilibrium solution exists, this problem can be solved as a non-linear programming problem using the method of Lagrange multipliers. The Lagrange expression is given by

$$L = (p - c/B)u + \lambda_1[s(B - u) + w - B] + \lambda_2[B - u - \xi_{min}] \tag{9}$$

where B and u now represent equilibrium levels. The Kuhn-Tucker conditions are

$$\frac{\delta L}{\delta B} = \frac{c}{B^2}u + \lambda_1 s - \lambda_1 + \lambda_2 = 0 \tag{10}$$

$$\frac{\delta L}{\delta u} = p - \frac{c}{B} - \lambda_1 s - \lambda_2 = 0 \tag{11}$$

$$\frac{\delta L}{\delta \lambda_1} = s(B - u) + w - B = 0 \tag{12}$$

$$\frac{\delta L}{\delta \lambda_2} = B - u - \xi_{min} \geq 0, \qquad \frac{\delta L}{\delta \lambda_2}\lambda_2 = 0 \tag{13}$$

From the dynamic constraint the equilibrium catch is given by

$$u = \frac{w - (1 - s)B}{s} \tag{14}$$

Substituting this into Eq. (13) and rearranging it is seen that

$$B > w + \xi_{min}s \tag{15}$$

with $\lambda_2 = 0$, or

$$B = w + \xi_{min}s \tag{16}$$

with $\lambda_2 > 0$. This is the minimum escapement constraint stated only with the biological parameter w, s and $\xi_{min}$. Assuming $\lambda_2 = 0$, i.e. assuming an interior solution, the optimal catch and biomass level can be found from the Eqs. (10), (11) and (12), and they are

$$B^* = \sqrt{\frac{cw}{p(1 - s)}} \tag{17}$$

and

$$u^* = \frac{w - \sqrt{(1 - s)cw / p}}{s} \tag{18}$$

Substituting B* and u* into Eq. (13), it is seen that this interior solution is only in effect if

$$\frac{c}{p} > \frac{(w + \xi_{min}s)^2 (1 - s)}{w} \tag{19}$$

otherwhise $B - u = \xi_{min}$, implying

$$B^* = s\xi_{min} + w \tag{20}$$

and

$$u^* = w - (1 - s)\xi_{min} \tag{21}$$

In other words, the escapement level will only be larger than the required minimum if the cost/price ratio is smaller than some value depending on the biological parameters w, s and $\xi_{min}$ [2]. In particular, if $\xi_{min} = 0$, condition (19) can be rewritten

$$\frac{c}{p} > w(1 - s) \tag{22}$$

The optimal equilibrium effort level will be given by E*= u*/B* which implies that

$$E^* = \frac{1}{s}\left[\sqrt{\frac{p(1 - s)\, w}{c}} - (1 - s)\right] \tag{23}$$

from Eqs. (17) and (18) when the minimum escapement is not binding, and

$$E^* = 1 - \frac{\xi_{min}}{s\,\xi_{min} + w} \tag{24}$$

when the minimum escapement constraint is binding.[3] However, for the purpose in this study the optimal equilibrium with constant recruitment is not of interest in itself, and is only meant to serve as a reference.

Comparing constant effort with constant catch will only be interesting if the fish stock biomass varies for some reason, and in this section the assumption will be that this variation is due to stochasticity in recruitment. The dynamics are still given by Eq. (1), but now the recruitment wt is a stochastic variable with expectation . However, if recruitment is a stochastic variable

and there is no stock – recruitment relationship at all, the optimal policy will be given by the optimal solution from the determinictic equivalent of the model. This is rather obvious since in this cas recruitment will be an additive stochastic variable in the dynmaic equation. The objective is to maximize the expected net present value of future income, and the dynamics can be written

$$\epsilon B_{t+1} = s(\epsilon B_t - u_t) + \mu \tag{25}$$

2. This value will be increasing with $\xi_{min}$, increasing with w given that $w > \xi_{min}s$ and decreasing in s given that $s > (2\,\xi_{min} - w)/3\,\xi_{min}$
3. These optimality conditions can also be found by maximazing the Lagrange expression
$L = (pB - c)E + \lambda_1[s(1 - E)B + w - B] + \lambda_2[1 - E)B - \lambda min]$ with respect to E and B.

$\epsilon$ is the expectation operator. The minimum escapement constraint may play a role here. If the constraint on minimum escapement is

$$\epsilon(B_t - u_t) \geq \xi_{min} \tag{26}$$

the optimal solution will be equivalent to the constant recruitment case with the constant recruitment w replaced by the expected recruitment . Adjustment in the initial and final period is not regarded here. In other words, it is assumed that the initial biomass is at the optimal equilibrium level B*. The optimal approach to this level, e.g. from a severly depleted stock level, is usually a so-called bang-bang approach when we are dealing with linear models. The above constraint on minimum escapement is simply that expected escapement in any period shall not be less than $\xi_{min}$. If this is replaced by the stronger condition that actual escapement in each period shall not be less than $\xi_{min}$, a more cautious policy is required. In this case the worst possible recruitment pattern must be taken into account, although the probability that such a recruitment pattern will in fact occur may be infinitely small. The expected recruitment, $\mu$, has to be replaced by the minimum recruitment, $w_{min}$. A policy based on $w_{min}$ will yield a much lower income than a policy based on since this policy probably will overshoot the minimum escapement goal. It will of course also yield a lower income than a policy based on this condition but where the catch and effort is free to vary from period to period. In this case knowledge about the stock level in each period may be used to assure that optimal effort is applied and at the same time the escapement level is not jeopardized.

Another way to put this is to say that a constant policy with respect to the control variable will only be optimal if knowledge about the current state of the resource is not available beyond period 0. In all other cases such knowledge may be used to improve the performance of the system.

Although the optimal solution is the same in the stochastic model as it is in its deterministic equivalent, the expected performances of the constant catch and the constant effort strategy may be different in the stochastic case. If expected recruitment is $\mu$, the expected biomass in each period will be . Suppose that the actual $B_t$ lies in the range [] which is symmetric around . Then the expected net revenue with constant catch will be

$$\epsilon\pi(CC) = \int_{B_L}^{B_U} (p - c / x)\, uf(x)dx \tag{27}$$

and with constant effort

$$\epsilon\pi(CE) = \int_{B_L}^{B_U} (px - c)\, Ef(x)dx \tag{28}$$

It can easily be shown (see appendix to this section) that $\epsilon\pi(CE) > \epsilon\pi(CC)$ when and the density function f(x) is a constant.

Another way the model above will show a difference in performance between the two strategies considered here is in the approach to the long term equilibrium given by Eqs. (17), (18) and (23). If there were no constraints on the adjustment to the equilibrium, a bang-bang approach would be optimal in this kind of model, meaning that zero harvest is applied if the biomass is below the level given by (17) and maximum harvest is applied if it is above this level, until B* is reached. However, here the problem is to find either the constant catch or the constant effort that is the best substitute for the bang-bang solution. If the time horizon tends to infinity, the optimal constant effort will approach E* given by (23) and the optimal constant catch will approach u* given by (18) for any c/p ratio satisfying (19) and any initial population satisfying the minimum escapement condition. E* and u* may, however, be zero if the c/p ratio is high enough.

With a relatively long but finite time horizon, T=100, numerical calculations confirm that constant effort yields better profitability than constant catch for all relevant values of c/p. In other words, with a long time horizon and stochastic recruitment constant effort is the better alternative. This also indicates that a constant effort policy is the best way to approach the long term equilibrium. This conclusion, of course, depends upon the assumption that all economic and biological parameters remain constant

Non-malleable capital and irreversible investments.

Another factor that may be of importance in the stochastic analysis is the role of investment in fixed (non-malleable) capital. There are two types of fixed capital ; namely perfectly irreversible investment decisions on the one hand and so-called quasi malleable capital on the other hand. In this paper it will be concentrated on the latter since perfectly irreversible investment implies a depreciation rate equal to zero which is not very realistic. Further, it is important to distinguish between fixed (capital) cost and variable (harvesting) costs. Analysis of optimal strategies in the presence of irreversible investments are made by Charles (1983a and 1983b) and Clarck et al. (1979). Some simplifying assumptions are made here, e.g. that the size of the stock is perfectly known at the beginning of each season eand that the necessary non-negative investments can be made immediately according to this knowledge.

In the model applied here the net revenue can be written :

$$\pi_t = pu_t(E_t, B_t) - VC(E_t) - FC(E_t^{max} - IC(I_t) \tag{29}$$

where VC denotes the variable cost function, FC the fixed cost function and IC the investment cost function. The news terms introduced here are $E_t^{max}$ which is the maximum capacity and $I_t$ which is the gross investment in period t.

There are two kinds of dynamics in the model ; the dynamics of the resource stock and the dynamics of the capital stock. Another way to put this is to say that the two types of capital, the resource and the conventional capital, are both included as state variables and the investment in both stocks, the catch rate and capital investment, are included as control variables. In each period

$$0 \leq E_t \leq E_t^{max}$$

where

$$E_t^{max} = (1 - \delta) E_{t-1}^{max} + I_t \tag{30}$$

and the gross investment, $I_t$, is defined as

$$I_t = \max(0, E_t(u_t, B_t) - (1 - \delta)E_{t-1}^{max}) \tag{31}$$

It is not possible to have negative investments in any period ; i.e., there is no second-hand market for capital (fishing vessels).

Assuming a particular model of the same kind that has been used earlier in this section, i.e., dynamics given by Eq. (1) and the production function given by Eq. (2), it is possible to derive some analytical results based on a deterministic version of the model. In particular it is possible to find the optimal equilibrium catch, effort and biomass level. In the optimal deterministic equilibrium there will never exist excess capacity nd hence fixed costs will play no role. The net revenue function can be rewritten

$$\pi_t = pEB_t - (c_v + c_i\delta)E \tag{32}$$

and optimal biomass, catch and effort will be given by Eqs. (17), (18) and (23) with c substituted by $(c_v + c_i\delta)$ where $c_v$ is the variable cost per unit of effort and $c_i$ is the investment cost per unit of capital. These values will be calculated and used as inputs in the stochastic model. The total net revenue from this model will also serve as a reference for the stochastic model. In the stochastic model the updating of fish-stock biomass can be given by

$$B_{t+1} = s\xi_t + w\epsilon_t \tag{33}$$

where is escapement and is a uniformly distributed random variable with expectation 1. That is, recruitment is a completely random, uniformly distribued variable with expectation w. Introducing irreversible investments and fixed costs will not after the situation under the constant effort strategy but will serve to decrease the profitability of constant catch. The interesting question then is how sensitive the profitability of the constant catch strategy is to changes in parameter values like $c_i$, $\delta$ and $c_f$ which is the per unit cost of excess capacity. These results are reported in Table 1. In

the initial model the economic parameter values are p = 1, $c_v$ = 6, $c_f$ = 3 and $c_i$ = 12. The depreciation rate, , is assumed to be 0.1 and the survival parameter s = 0.8. The optimal biomass, catch and effort from the deterministic equivalent of the model are reported as B*, u* and E* respectively. J denotes the accumulated net revenue over a time periodof 50 years. When stochasticity is introduced, 100 different recruitment patterns are drawn with expected recruitment 4 and standard deviation 2. The 95% confidence interval for the average accumulated net revenue with these recruitment patterns can be calculated as $J \pm 2s / \sqrt{n}$ where n = 100 and is the standard deviation for J (Rubinstein, 1981). These intervals and the average J are reported in the rightmost column in Table 1.

$c_f$ is supposed to be significantly less than $c_v$ since it is less costly to have idle fishing vessels than it is to actually use these fishing vessels. In the initial model $c_f = 0$ and $c_f = c_v$ is applied. The deterministic optimum and the profitability of CE is independent of $c_f$.

If $c_i$ and $\delta$ are changed in a way that $c_i\delta$ remains unchanged, this will not have any effect on the deterministic model or on the profitability of the CE strategy, but the profitability of the CC strategy may be affected by the mix of $c_i$ and $\delta$. In the simulations reported in the table $c_i$ and $\delta$ is reduced by 50%, one at a time. The profitability of CC increases faster when $c_i$ is reduced than when $\delta$ is reduced. That is, the constant catch strategy is more sensitive to a change in the cost of investment than to a change in the depreciation rate. It is not intuitively clear why this is so. Part of the explanation is that higher increased $c_i$ will either reduce the profitability due to higher costs when investment takes place or have no effect at all when no investment takes place. An increased depreciation rate will reduce profitability when investment takes place simply because higher $\delta$ implies higher investment. On the other hand, when the level of fixed capital is already too high, increased will reduce fixed costs because it implies some degree of disinvestment and thus it will increase $\delta$ the profitability.

It is also of interest to compare these results with the result of using the alternative production function given by $u = u = B(1 - e^{-E})$. The effort requirement function, which is the inverse of the production function, becomes

$$E = \ln\left(\frac{B}{B - u}\right) \tag{34}$$

The escapement in the case of constant effort is now written :

$$\xi_t = B_t e^{-E} \tag{35}$$

With this production function the optimal equilibrium effort, E*, in the deterministic model is given by

$$E^* = \ln\left[\frac{-s^2c}{\sqrt{p^2w^2M^2 + 4scpwM - 2sc - pwM}}\right] \tag{36}$$

$M \equiv (1 - s)$ and $c = (c_v + c_i\delta)$. This value can be substituted into the production function in ordrer to find u* and into

$$B^* = \frac{w}{1 - se^{-E^*}} \tag{37}$$

in order to find the optimal equilibrium stock. The parameter values are changed such that $c_v$= 5 and $c_i$ = 10. It is interesting to note that the introduction of this production function does not make any big difference compared to the other results reported in the table.

It is common for all the results that the regions (95% intervals for average net revenue) are not overlapping. Further, the regions with constant catch do not in any case include the net revenue resulting from the deterministic model whereas the regions with constant effort do not onlu include this value, but the average J is higher in all cases. In other words, there is a positive cost of stochasticity with constant catch, and this cost increases with fixed costs but it is positive even when $c_f = 0$. With constant effort the cost of uncertainty is not significantly different from zero.

It may be even more interesting to combine irreversible investments with the presence of a spawning stock / recruitment relationship. A Beverton-Holt recruitment function is applied for this purpose. This function is given by

$$w_t = \frac{\alpha \xi_t}{1 + \beta \xi_t} \tag{38}$$

In this case it is not easy to find an analytical expression for the deterministic optimum. The optimal equilibrium can, however, be calculated using numerical methods. With the same economic parameter values as in the initial model and = 1 and = 0.1 in the B-H recruitment function, the result is : E* = 0.139, B* = 20.55 and u* = 2.85. Net revenue in each period is 1.85. The problem now is that in 12 out of 100 simulations, the CC strategy is not feasible bacause the stock ultimately becomes smaller then the allowable catch. In other words, the stock will get extinct if this strategy continues. Higher costs will reduce the optimal catch rate and increase the probability that CC is a feasible strategy. The result reported here is calculated using the following values : $c_v = 10$, $c_f = 10$, $c_i = 20$ and in this case the stock does not get extinct. Now E* = 0.107, B* = 23.84, u* = 2.55 and J* = 63.21.

The confidence intervals are

| | |
|---|---|
| CC [57.45, 60.70] | J = 59.07, |
| CE [61.47, 63.94] | J = 62.71. |

The only noticable difference from the results reported earlier is that the average J with the CE strategy is less than J* from the deterministic optimum.

Another interesting aspect of including non-malleable capital is that it is no longer obvious that the argument about risk aversion being in favour of constant catch holds true. This argument is based on the assumption that net revenue with constant catch will have less variance than net revenue with constant effort, but when there are fixed costs pertaining to investments and the biomass is varying stochastically, this assumption may be false. The argument above is only valid if it is plausible that a low variance of net revenues outweighs a lower value of the average net revenue. Calculations of the average variance of net revenue based on 100 different stochastic recruitment patterns with the initial model mentioned above, show that whereas . It is important to note that the increased variance of the CC strategy is entirely caused by the investment costs and not by the fixed costs of having excess capacity. The fixed costs of excess capacity actually work in the opposite direction ; that is to reduce the variance. This can be explained as follows. In a period when the biomass level is lower than the equilibrium, there is a need for new investments in fishing effort in order to take the constant catch which will make the already low profit in this period even lower, thus increasing the variance of net revenues. In such a period there will be no excess capacity costs. On the other hand, when the biomass level is higher than the equilibrium level, there will be no need for new investments but the excess capacity costs will reduce the net revenue which already is higher than average, and therefore the variance of net revenues will be reduced. It is clear from this that the higher ci and the lower $c_f$ is, the higher the variance with the CC strategy will be. It seems reasonable to suggest that $c_i$ is high relative to $c_f$, or in other words, that the buying cost per unit effort is higher than the per unit fixed cost of idle effort.

## 3. CONCLUSIONS

In general one would expect the constant effort strategy to be more profitable than constant catch. There are, however, many factors that can modify this and make constant catch more desirable. Such factors include everything that makes net revenue concave in catch, e.g. risk-aversion on behalf of fishermen or economies of scale (decreasing marginal cost).

The conclusion when there are irreversible investments in fixed capital is, not unexpetedly, that this will significantly reduce the profitability of the constant catch strategy. Even an —assumption of strong risk aversion will not be able to reverse this conclusion. The analysis above assumes somewhat unrealistically that new investments can be made almost instantaneously. This of course is not true, but it makes it easier to illustrate the main effects of having non-malleable capital.

ABSTRACT

*In this paper, the basic principles of chaos theory are applied to dynamic systems involving renewable resource and harvest. The results of simulations are presented regarding harvested resource stock time path. It is shown that stationary steady-state is only one of many different possible outcomes of bioeconomic equilibrium. The varying impacts that different management policies have on an unstable dynamic system are also studied. It is shown that in unstable resource systems, the effects of some policy measures will be very different from the ones obtained through traditional resource analysis. It also shows that policies which induce a stabilizing effect in stock time series will generally provide greater welfare gains. the results are illustrated by two market examples.*

## 1. INTRODUCTION

In renewable resource analysis the main focus has been to first identify and characterize stationary states. A totally different approach comes from Chaos Theory. Basically it shows that simple deterministic but nonlinear relationships are able to generate complex time series behavior that ranges from stable trajectories to a form of instability known as deterministic chaos. A clear description of Chaos Theory and its relevance to economic analysis is presented in Baumol and Benahabid (1988). Its most revealing feature is demonstrating that the source of instability can be within the dynamic system itself, depending on the values of certain parameters.

To apply this framework to renewable resource analysis seems an obvious step, as nonlinearity is one of its more important characteristics. Simulations of time series behavior of an unexploited resource stock, using chaos theory, were first presented by May (1975). Here, the usual assumption of a stable carrying capacity for a unexploited is questioned. However, since then no further analysis on this subject has been published.

The main purpose of this work is to extend May's analysis to a harvested resource stock, i.e try to establish how harvest affect the time path of a resource stock. When harvest is introduced, the dynamic system that rules stock time series is altered. Previous stable trajectories can become unstable or vice versa. Notice, that total harvest each period is determined by market forces and/or by policy regulations. Hence, market parameters and regulation measures in the harvest industry do affect stock behavior. In return, the induced stock behavior can alter the effectiveness of certain policy measures.

The paper is organized in the following way : in section 2 the results for simulations of different harvest conditions are presented and the impact of some regulatory measures is shown. In section 3 two different market examples illustrate the possible implication for policy effectiveness of this new approach, and finally section 4 presents some concluding remarks.

## 2. DYNAMICS OF A RESOURCE STOCK

### *2.1 Dynamics of an Unexploited Resource Stock*

To illustrate the chaos phenomenon (as reported in Conrad & Clark(1987) following the work of May(1975)), let the Logistic function represent the dynamics of an unexploited resource. If written as a differential equation, it takes the form :

$$\dot{X} = rX_t(1 - X_t/K)$$

where $X_t$ is the stock in period t, r is called the intrinsic growth rate and K represents the environmental carrying capacity. In the absence of catch $X_t \rightarrow K$ from any $X_0 > 0$ as $t \rightarrow \infty$, and K is a globally stable equilibrium. If written as a difference equation :

$$X_{t+1} - X_t = r\,X_t\,(1 - X_t/K)$$

one might expect the discrete time analog to exhibit the same properties. However, this nonlinear difference equation is capable of producing much more complex behavior depending on the value of r. For this equation specifically :

If, $0 < r < 1$ - The population steadily approaches K.

If, $1 < r < 2$ - The population overshoots but undergoes dampened oscillation as it approaches K.

If, $2 < r < 2.449$ - The population settles down in a two point cycle.

If, $2.449 < r < 2.570$ - The population achieves a stable cycle with $2^n$ points.

If, $r > 2.570$ - The population behavior is referred to as dynamic chaos.

In dynamic chaos, time series have an appearance of disturbance by random shocks and undergo abrupt qualitative changes. Chaotic time paths are very sensitive to initial conditions and to small changes in the values of the parameters.

A variety of functional forms can be used to specify the resource growth function. Two different functions will be analyzed in order to illustrate the sensitivity of some results.

Logistic Function

$$X_{t+1} - X_t = rX_t\left(1 - \frac{X_t}{K}\right)$$

Gompertz function :

$$X_{t+1} - X_t = rX_t \ln\left(\frac{K}{X_t}\right)$$

Both generate the same kind of time paths as the ones described above for the logistic function.

*2.2 Dynamics of a harvested resource stock*

We will, now, address the following questions : What would be the behavior of a harvested resource stock ? How can harvest intensity affect the time path of the resource ?

With harvest, stock time series are given by the following equation :

$$X_{t+1} = X_t + H(X_t) - C_t$$

where $H(X_t)$ is the resource growth function, and Ct is total harvest in period t.

It is reasonable to assume that harvest in period t also depends on the stock level, either because of induced changes in harvest intensity or because of changes in harvest productivity. Simulations were carried out for different catch stock relationships, and for different levels of harvest intensity. Different market and institutional conditions can support all of the case studied Some examples will be presented at the next section.

### 2.2.1 Linear catch-stock function

Assuming a linear catch-stock function means that variations in catch are proportional to variations in stock levels. In this case, stock time series are calculated from the equation :

$$X_{t+1} = X_t + H(X_t) - C_t$$

where c is a constant [1]and represents the level of harvest intensity.

In this case the following results apply : for the Logistic function any catch level will produce a stabilizing effect in stock time series. On the contrary, with the Gompertz function, stock instability is maintained. To illustrate these results let us look at the two extreme cases : a stable unexploited stock(r=0.8), presented in Fig 1, and a chaotic unexploited stock (r=2.7), presented in Fig 2(a) and Fig 2(b) [2].

In the first case, stock will more or less rapidly stabilize at long run equilibrium level. Here, a stable unexploited stock remains stable. If we look at a chaotic unexploited stock, the result is not the same for the different growth functions. As shown in Figure 2(a), harvest stabilizes the time path of the resource stock when resource growth is represented by the Logistic function. In addition, the stabilization effect is greater, the greater the catch level [3]. On the contrary, as shown in Figure 2(b), for the Gompertz function, a chaotic unexploited stock remains chaotic when catch is introduced.

### 2.2.2 Convex catch-stock function.

A convex catch-stock function assumes that the variation in catch is more than proportional to variations in stock ; here, the resource time path can be represented by :

$$X_{t+1} = X_t + H(X_t) - cX_t^{\delta} \text{ with } \delta \geq 1$$

The simulation results can be summed up as follows : a convex catch-stock relationship will de-stabilize stock time series, the greater the degree of convexity, and the greater catch intensity. Qualitatively, the results are similar for the two specified functions, but the de-stabilizing effects are stronger in the Gompertz function.

1. The value of c can be greater than 1, if r is also greater than 1. Catch can not exceed initial stock plus growth during that period.
2. Catch intensity, in each case, is the level corresponding to the continuous time analog equilibrium for X=20,000.
3. For a small catch intensity (c=.54) the stock stabilizes in a two point cycle ; but for a greater catch intensity (c=1.62) the population rapidly approaches an equilibrium value.

Figure 3 represents stock time path simulated by the Logistic function, for r=2.7. It compares the linear catch-stock function with a convex catch-stock function and as shown, harvest no longer induces a stable stock trajectory. For greater levels of catch stock elasticity ($\delta > 2.3$), the stock time path becomes cyclical [4] or explosive. Also, for different levels of catch intensity time paths remain chaotic, as illustrated in Fig 5.

Even if unexploited stock is stable, a convex catch-stock function is able to produce chaotic behavior, although for higher levels of stock convexity. It is shown in Figure 4, for the Gompertz function The Logistic function also produce similar patterns but for much higher levels of convexity.

Also, the stock time path becomes less stable, the greater the catch intensity. In Figure 6, this result is illustrated for the Gompertz function.

### 2.2.3 Concave catch-stock function

A concave catch-stock relationship assumes that the variations in catch are less than proportional to variations in stock. Here, stock time series will be generated by the equation :

$$X_{t+1} = X_t + H(X_t) - cX_t^{\delta} \text{ with } \delta \leq 1$$

In general, a concave catch-stock function has a stabilizing effect in stock time series, for all growth functions. However, the steady path can either be to equilibrium or to extinction. The range of initial value of the stock level that induce a steady decrease to extinction is enlarged.

With the Logistic function, a concave relation implies an asymptotic approach towards long-run equilibrium, and this is true even for a chaotic unexploited stock (r=2.7). For the Gompertz function the general stabilizing effect is qualitatively the same but less intensive. In Figure 7 a linear catch is compared with a slightly more concave catch, and this is sufficient to change a chaotic time path into a two point cycle trajectory. In all cases the stabilizing effects are greater, the greater the catch intensity.

### 2.2.4 Constant catch

Assume now that total catch is constant. In this case, the stock time series will be determined by the equation :

$$X_{t+1} = X_t + H(X_t) - \mathbf{C}$$

where C is a constant catch level.

In all the examples studied a constant catch will induce a stabilizing effect in the stock time series, and this effect is greater, the closer the catch is to the Maximum Sustainable Yield (MSY). These results are illustrated in Fig 8,9, and 10.

Going through all these cases, has shown that harvest can in fact change stock time path behavior. It can augment, maintain or diminish resource time series fluctuation, and it depends not only on the harvest parameters but also on the specific underlying growth function.

In spite of the sensitivity of the time path, to the model structure, to the values of the parameters and to the initial starting points, some order exists behind all the results of the simulations. For the same values of growth function parameters we can say that the more concave the catch- stock relation, the more stabilizing the harvest is. Also, the more skewed to the right the underlying resource growth function is, the more stabilizing the harvest is, for high levels of catch intensity. In addition, the more stabilizing the harvest is, the smaller the range of initial stock values that produce positive time series.

## *2.3 Dynamics of a Regulated Resource Stock*

Most commercial renewable resource systems are presently subject to some form of regulation, so in this section, we will try to give an answer to the following questions : How do management regulation instruments affect resource stock behavior ? Does it affect policy effectiveness ?

4. This cyclical pattern occurs only if the simulation negative values are changed to arbitrary small values. Alternatively one can assume stock extinction.

In a deterministic context the evaluation of different policy measures is traditionally based on time continuous analysis. It is then generally assumed that, whatever the policy implemented, stock would in any case grow asymptotically towards the new equilibrium. Policy evaluation is then based on comparative static analysis. In the present context, it will be shown that different policy instruments, will affect the dynamics of the system in different ways, either enlarging or reducing the previous stock instability. This will have to be taken into account when evaluating policies from a welfare point of view.

### 2.3.1 Policy 1- Proportional Quota

If a resource stock is managed through annual catch quotas the catch-stock relation is no longer determined by market conditions but by some pre-determined rule. A constant fishing mortality implies that catch is a fixed proportion of stock.

Let us then consider that the annual catch quota is fixed each period according to the following rule : $TAC_t = f\ X_t$, where f represent a constant fishing intensity. If such is the case, all of the results of section 2.2, for the linear catch-stock case, apply.

However, what usually happens is that the TAC for each season is established before the season opens. Suppose it is based on stock surveys of t-1 period, in this case, the annual catch quota is given by : $TAC_t = f\ X_{t-1}$. Stock simulations will be derived from the equation :

$$X_{t+1} = H(X_t) - X_t - f\ X_{t-1}$$

If unexploited stock is unstable, this small change can have a significant impact in simulation results. In Figure 13(a), the stock time series in simulation map called "Prop. TAC" assumes that the TAC is ruled by the first equation and the one named "Lagged TAC" assumes it is ruled by the second equation [5]. In such circumstances this policy will not have the stabilization effect that could be found in the linear catch case.

If unexploited stock is stable, a lagged policy, compared to a linear TAC, will have a minor effect on stock time series. In case of the logistic function, it will even speed up stock adjustment to long run value. However, in general terms, lags in the regulatory process can have de-stabilizing effects in stock time series, and in some cases even result in stock extinction.

### 2.3.2 Policy 2 - Constant Catch Quota

As seen in section 2.2. a constant catch will always have a stabilizing effect on stock time series. For levels of catch near M.S.Y. the time path of the stock level is a stable one. However, high levels of constant catch are not possible if initial stocks are low, in which case time trajectory will drive stock to extinction. This is not a serious policy limitation because lower catch level can be set initially and augmented as stock recovers.

The stabilizing effect of a constant catch is one of the most surprising results [6] of the present analysis. This aspect establishes some advantages in relation to the proportional TAC as the stabilizing effects are independent of the specific growth function used. In addition, the problems derived from the lags in the regulation process are, in this case, irrelevant ; stock surveys are no longer necessary. Also, in all of the cases studied, welfare gains from this policy are always equal to or greater than the ones resulting from a proportional TAC. In addition, they are also always greater than the ones resulting from a lagged TAC.

### 2.3.3 Policy 3 - Licenses

Assume now that a limit is imposed on the number of units allowed to harvest the resource stock. In this case, the policy instrument does not by itself establish a particular catch-stock relationship. The impact depends on the underlying fleet-catch function.

5 In addition, it assumes that the market has a corrective effect, allowing that in bad stock years the TAC will be left unfulfilled if catch is not profitable. Otherwise this rule would drive resource to extinction.

6. Surprisingly from a policy evaluation point of view, because mathematically it is quite obvious.

If the boat catch function is linear in stock, entry restriction will maintain a linear catch-stock relationship, but at a lower level of catch intensity. The results presented for the linear case apply.

If boat catch function is concave in stock, then boat licensing does not change the degree of concavity of the catch-stock relation. In this case the stabilizing effect will be maintain.

### 2.3.4 Policy 4 - Tax on catch.

In the present framework, a tax on catch is the most unpredictable instrument, as it rely on market mechanisms.

Consider first the case where the number of harvest units is fixed. Here, a tax will impose heavy losses in the first periods. If resource price is constant, it will in most cases stop harvesting for one or two periods. If price varies according to a given demand function, a rise in price will maintain some harvest in the initial periods, as long as marginal revenue is greater than or equal to marginal cost. What happens next is always uncertain because it depends on how many boats remain active and for how long. Assuming that all units are identical, there exists no market mechanism to determine the intensity of the industry reaction. After the adjustment, the catch-stock relation will be determined by the underlying boat catch function.

If, on the contrary, the fleet in each period is determined by market equilibrium, a tax on catch will lower the market producer price, and catch intensity is immediately adjusted. The effect on stock time path behavior will, in this case, depend on market characteristics. It generates a totally different outcome whether the tax is a unit tax or an ad valorum tax.

To conclude, except for the constant TAC policy, all the other studied policies will have variable effects on stock behavior depending on both on unexploited resource behavior and market conditions.

## 3. POLICIES EFFECTIVENESS : MARKET EXAMPLES

In order to illustrate some of the above results, and clarify the way markets and regulation affect resource growth behavior, we present two numerical examples. Before proceeding, it should be recalled that one of the characteristics of chaotic dynamic systems is their sensitivity to parameters and initial point values, so the particular values of the simulation results presented have a limited significance. However, as pointed out in Baumol et al. (1988), "despite their sensitivity, they can be effective instruments for disproving the universal validity of some propositions and so *provide warnings to policy designers*". Some of the more interesting results will be presented, first, to point out some cases were policy regulations do not afford the desired welfare gains, and second to show that some apparently equivalent instruments may not be equivalent at all.

Simulations of the industry evolution, in both markets, for different regulation measures, were carried for a twenty-five year horizon, and welfare gains and losses were added using a 1 % discount rate. The results are presented in Figures 12 and 13 for example 1 and Figures 15 and 16.for example 2. The examples assume chaotic growth functions because this case provide the greatest variety of possible situations [7]. Also, the specific values of each regulation measures have a common objective : the continuous time analog, that induce stock and catch to stabilize at :

Logistic function : $X = 30\,000$ ; $C = 32\,400$ ("c" in Figure 11)

Gompertz function : $X = 33\,000$ ; $C = 36\,200$ [8] ("d" in Figure 11)

Aggregate welfare gains or losses will depend on the specific market conditions as summarized in Table 1.

### *3.1 Example 1- Linear catch-stock relation*

Suppose an open access fishing industry characterized by the following relationships :

$$C_t = N.C_{it},\ C_{it} = q.E_{it}.X_t,\ \pi_i = P.C_{it} - wE_{it} - F \quad i = 1,.....,N$$

7. As seen, stable unexploited stocks will generally, remain stable, except when catch-stock relation is convex.
8. This is equivalent to a catch intensity of c = 1.08

where N represents a fixed number of boats, Cit is the catch per boat, q is a constant catchability coefficient, Eit is effort per boat, Òi is the profit per boat, P represents the resource market price, w is constant cost of effort and F is a fixed cost. As catch function per boat is linear in relation to stock level, harvest from this particular industry can be represented by a linear catch stock in active years. Being N = 100, $E_{i\ Max}$ = 200, q = 0,000108, P = 25, w = 2 0, F = 1400, the constant capture coefficient c will be 2.16.

If the system is globally stable, continuous time analysis assumes that resource stock will tend asymptotically to long run equilibrium, as represented in Figure 11. Long-run equilibrium values for the two growth functions would be respectively :

Logistic function : C = 21,600, X = 10,000, $\pi_i$ = 0 ("a" in Figure 11)

Gompertz function : C = 48,526, X = 22,466, $\pi_i$ = 6,731[9] ("b"in Figure 11)

With the Logistic function, the result of the industry simulations in a discrete time context is the same,(Figure 12(a)), with the resource stock, total catch, and profits approaching asymptotically the above equilibrium values [10]. Most policies will imply the same results as continuous time analysis. However, two exception occur, with the tax on catch and the lagged linear TAC (see Figure 13(a)).

Here market equilibrium is a stable equilibrium and a proportional TAC will also maintain a stable stock, profits will grow and rapidly stabilize at 4,700. If there is a lag in establishing the quotas for each harvest season, the scenario will be quite different. As can be seen the de-stabilizing effect on stock time distribution, induce profits instability. For the case studied, average profits are now lower, at 2,266. Compared to the open-access equilibrium where profits are zero, a lag in the regulating process will still have a positive welfare gain [11], although smaller than the one resulting from a linear TAC. However, if agents are risk averse, the certainty equivalent [12] value of profits can be negative. To conclude, if agents individually are risk neutral, this policy can produce some welfare gain, but if they are risk averse, the increase in expected profits can be offset by the increase in profits uncertainty.

The tax case presented assume that the entire fleet will be active for the first four periods. From then on the fleet is adjusted to the level necessary to perform the policy objective (f = 1.08). We choose this particular solution as a reference point, but it should be clear that there is no market mechanism that would induce this specific outcome. This policy produce an unstable catch path, whenever the entire fleet remains active. Once the assumed fleet adjustments are completed, stock will stabilize only after seven periods of time. From a welfare point of view, and if agents are risk neutral this particular simulation will result in a welfare gain : profit losses are smaller than tax revenue.

If we look at the same market conditions but with a different underlying resource growth function, the simulation results will be quite different. As can be seen in Figure 12(b), a linear catch-stock relation does not stabilize stock. The market stock time trajectory is unstable [13]. For the same reason, all policies except the constant TAC will result in unstable time series (Figure 13(b)).

This fact will imply different welfare considerations on the impact of some policy measures. Here, all policy measures will result in welfare losses except the constant TAC policy. Only in this case the actual value of the stream of profits is greater than in market equilibrium

With the proportional TAC the actual value of the stream of profits is smaller than in market equilibrium, so if agents are risk neutral there will be a loss in welfare. However, if agents are risk averse, the certainty equivalent value of profits

9. This case is not an open-access equilibrium, because profits are stable and positive, creating an incentive for new agents to enter this industry.
10. In fact according to section 2, a linear catch stock relation stabilizes stock time series.
11. As price is constant, variations in industry profits represent all possible welfare gains
12. By certainty equivalent we mean the constant value of profits that would generate in twenty five years the same level of utility as the actual profit distribution, that is :
$\pi$ such as $\Sigma\ U(\pi t) / (1 + r)^t = \Sigma\ U(\pi) / (1 + r)^t$
with $U(\pi) = (1 - e^{-\sigma\pi}) / (1 - e^{-\sigma})$ being $\sigma$ a measure of risk aversion.
If agents are risk neutral $U(\pi t) = \pi t$, and $\pi$ is given by :
$\pi$ such as $\Sigma\ (\pi t / (1+ r)^t) = \pi\ \Sigma\ 1 / (1+ r)^t$
13. In this particular simulation, average profits are still positive although lower than the continuous time equilibrium value. Unless agents are risk averse, this simulation does not represent an open-access equilibrium. If agents are risk averse, the certain equivalent value of that particular profits distribution is zero for a constant risk aversion equal to 0,00086885.

is positive ($\pi = 52$) and greater than the certainty value of market equilibrium($\pi \approx 0$). So, from a welfare point of view, the TAC regulation is worse if agents are risk neutral, but can have some welfare gains if agents are risk averse. This can be explain by the fact that while maintaining stock instability, the TAC has, in this case, reduced profits variance.

If a lag exits in the establishment of the TAC, it will enlarge stock instability. In this case the welfare loss that result from this policy will even be greater.

The licensing will produce a time series stock behavior similar to the proportional TAC. From a welfare point of view the result is also similar, there will be higher profits per boat but less number of boats.

A tax will also produce a cyclical catch, whenever the entire fleet remains active. But after the assumed fleet adjustments stock will still remain unstable. In this case a tax will produce a welfare loss, here loss in profits are bigger than tax revenue.

### *3.2 Example 2 - Convex catch-stock relation*

Suppose now an open-access fishing industry characterized by the following parameters :

$$C_t = N.C_{it},\ C_{it} = q.E_{it}.X_t,\ \pi_i = P_t.C_{it} - wE_{it} - F,\ P_t = a(C_t)^{-\beta}$$

Let us also, assume that an unlimited number of boats can enter this fishing activity at a fixed cost F, so that, the number of active boats is in each period determined by market equilibrium. Specifically :

$$\pi_t = 0 \Rightarrow N = (a/(wE_t + F))^2\ qE_iX_t$$

In this context, market clearing will maintain profit per boat and industry profits near zero, but this market is characterized by a fluctuating fleet, price and catch. Welfare gains from the different policy measures will be measured by industry profits plus the change in consumer surplus.

If $E_{i\ Max} = 200$, $w = 20$, $F = 1{,}400$, $a = 3674$, $\beta = 5$ the catch-stock relation is convex and given by :

$$C_t = (aqE_i/(wE_i + F))^2\ X_t^2 = 0.00021597242\ X_t^2$$

Figure 14 represents market equilibrium derived from time continuous analysis. Long-run equilibrium values for the two growth functions would be respectively :

Logistic function : $N = 100$, $P = 25$, $C = 21{,}600$, $X = 10{,}000$. ("a" in Fig.14)

Gompertz function : $N = 150$, $P = 16.(6)$, $C = 48{,}000$, $X = 15{,}000$ ("b"in Fig.14)

However, as could be expected from section 2.2, a convex catch-stock relation market equilibrium will in both cases provide an unstable stock time series.(see Figure 15).

With the underlying Logistic function most policies will change the market convex catch-stock relation in a linear catch-stock relation. This will stabilize stock time trajectory and produce the same results as continuous time analysis. Again, two exception occur, with the tax on catch and the lagged linear TAC as can be seen in Fig 16(a).

Under these market conditions, a tax interfere in the fleet adjustment process, and the choice between a unit tax and a percentage tax will have very different results. The reason being that with a unit tax the catch-stock relation becomes concave, on the contrary, the percentage tax maintains a convex-catch stock relation [14]. This way, a unit tax can have a

14. With a unit tax, market equilibrium catch will be given by :
$C_t = (a/wE_t + TqE_tX_t)^2\ (qE_tX_t)^2$
and the degree of convexity is smaller. Catch-stock relation can even become concave at high stock levels. With an ad valorem tax, market equilibrium catch will be :
$C_t = ((1 - t)a/wE_t)^2\ (qE_tX_t)^2$
which maintains the convexity of the catch-stock relationship, although at a lower level of catch intensity.

stabilizing effect on stock behavior, which will not occur in an equivalent ad valorem tax. It results that, from a welfare point of view, a unit tax will always present higher welfare gains than a percentage tax. The difference in welfare gains between the two instruments is enlarged if agents are risk averse.

With the Gompertz function, these particular market conditions will drive stock to extinction in three periods of time. Alternatively, it can be assumed that stock is never extinct but only severely depleted. In this case, market simulation results in a three-period cyclical harvest, as shown in Fig 15(b). In this case, all policies except the constant TAC and the unit tax will result in unstable time series (see Figure 16(b)).

The establishment of a proportional TAC, will result in a more stable time path, but will also eliminate the occasional profits that occurred in open access. As on the consumer side the TAC will produce a small loss in consumer surplus, the TAC will be worse than market equilibrium. With the lagged TAC welfare loss will be even bigger.

The licence scheme, although producing the same effect on stock and catch time series as the proportional TAC has a different result from a welfare point of view. In this case, some profits are generated in the industry, and in spite of the small loss in consumer surplus there will be a welfare gain from this policy.

Again, a unit tax have a stabilizing effect on stock behavior, which will not occur in an equivalent ad valorem tax. In this case a unit tax will produce a four period cycle behavior in stock time series while the percentage tax will maintain a unstable stock. It results that, from a welfare point of view, a unit tax will also present higher welfare gains than a percentage tax.

Most actual management policies are implemented to preserve resource stocks from extinction, however, within the present framework and looking from a conservation point of view, some policies will not have the desired effect.

## 4. CONCLUSIONS

First of all, it should be clear that all of the results derived from this study depend on the validity of the Chaos theory to explain real resource stocks behavior. Notice however that in many scientific fields, including biology and economics, chaos theory has played a growing role as an alternative approach to understanding reality.

In general terms, this approach enlarges the theoretically possible impacts of harvest in the resources time series behavior. As shown, harvest can augment, maintain or diminish resource time series fluctuations.

In spite of the sensitivity of the time path to the model structure, to the values of the parameters and to the initial starting points, some order exists behind all the results of the simulations. For the same values of growth function parameters we can say that the more concave the catch- stock relation, the more stabilizing the harvest is. Also, the more skewed to the right the underlying resource growth function is, the more stabilizing the harvest is, for high levels of catch intensity. In addition, the more stabilizing the harvest is, the smaller the range of initial stock values that generate positive time series.

From all that has been said we may also conclude, that policy design in renewable resource markets is much more complex than could be expected from traditional deterministic analysis. Although generalizing results are somehow contradicted, some insights are gained which will help in the choice of policy when confronted with a particular real situation.

The most interesting result here is that, in unstable resource systems, the effects of some policy measures will be very different from the ones obtained through traditional resource analysis. It also shows that policies which induce a stabilizing effect in stock time series will generally provide greater welfare gains.

In relation to specific policy measures, a surprising result is the argument in favor of the most criticized management policy in economic literature : the Maximum Sustainable Yield (MSY). As has been shown a constant catch policy in all cases induces a stable stock for values of catch near the MSY. Under certain market conditions this instrument generates the highest welfare gains if compared to equivalent policy measures.

This argument can also bring an additional insight to the recent theoretical discussion over the management policy options : Constant Catch Quota or Constant Effort (see Hanesson (1988)). The choice between these two options is seen

as a choice between stability in catch, necessary for the processing industry and stability in fishing industry profits. Here, a constant catch quota will in all cases stabilize stock time series, stabilizing at the same time total catch and individual fisherman profits. If alternatively a constant effort policy is chosen, it can no longer be insured that it will stabilize stock.

Also, it was shown that, taxes and lags in the regulating process can be an additional source of instability in stock time series. In some cases, those policy have opposite effects than the expected, both from an economic and a conservation point of view.

# Individual Fishing Rights : Some Implications of Transferability

**Parzival Copes** *

[a]Institute of Fisheries Analysis and Department of Economics, Simon Fraser University, Burnaby, B.C. V5A 1S6, Canada

ABSTRACT

*This paper analyzes the differential impacts of transferable (i.e. freely marketable) and non-transferable (i.e. granted for lifetime or limited term) individual fishing rights in respect of two interacting features : 1) the process of fisheries rationalization and 2) the achievement of a lasting improvement in fishing incomes. It traces the probable impact of transferability both for limited entry and individual quota regimes, noting similarities and differences.*

*With respect to rationalization, the paper concludes that transferability, by comparison with non-transferability, generally hinders implementation in the case of a limited entry regime, but helps it in the case of an individual quota regime. However, in the case of both regimes transferability leads to a "transitional gains trap", thereby impacting negatively on the prospects for a lasting improvement in fishing incomes.*

*The paper also comments on the particular merits of limited-term fishing rights in the case of both regimes.*

## 1. INTRODUCTION

Historically, most fish stocks have been exploited as common property resources under conditions of open access. Almost invariably this has involved excessive inputs of capital and labor in relation to output, resulting in dissipation of available resource rents (Gordon 1954). To restore such rents, and thereby improve economic performance, economists in recent decades have brought forward proposals for fisheries rationalization. These usually have involved either limitations on fishing inputs through limited entry licensing, or limitations on access to fishing outputs through the allocation of individual quotas (Scott and Neher 1981).

* In writing this paper the author has benefited from financial support provided by the Social Sciences and Humanities Research Council of Canada and from valuable research assistance by Don Reddick.

There are examples to be found of fishing operations that obtain good returns and of some that generate spectacularly high incomes. But it has been widely recognized that fishing communities throughout the world more often have suffered from low incomes relative to other groups in the same society (Copes 1987). For that reason the real problems of the fishing industry are socioeconomic as much as they are economic. An improvement in fishing income levels typically has a high priority in programs of economic reform for the fishing industry.

It is debatable to what extent low fishing incomes may be attributed directly to common property resource problems (Copes 1987). However, it is evident that a successful program of fisheries rationalization to remove or attenuate these problems could generate rents which might be used to alleviate the low incomes of fishers.

Economists have emphasized that the common property problems of the fishery are related to the nonspecification of property rights. Limited entry licenses and individual quota allocations represent forms of partial property rights, designed to overcome some of the misallocation of resources inherent in common property fisheries. However, the specific conditions qualifying the application of these rights may have considerable bearing on the success of any scheme of rationalization in meeting the dual objectives of a lasting regeneration of rents and a lasting improvement of income levels in the fishery. This paper will concern itself, specifically, with the crucial difference between the effects of transferable and non-transferable rights in this matter. It will also explore the application of limited-term fishing rights as a further alternative.

## 2. THE OBJECTIVES OF RATIONALIZATION

In the preceding section two major problems were identified that could be addressed by the rationalization of common property fisheries, viz., the regeneration of resource rents and the raising of low fishing incomes. Many economists, particularly among those devoted to formal theoretical analysis, have been preoccupied with the efficiency problem to the exclusion of distributional considerations, and accordingly have focused their attention on the maximization of resource rents. Johnson and Libecap (1982) captured this predilection in their observation that the "... inefficiencies of common property fisheries are of continuing concern to economists."

Not surprisingly, fishers, and the politicians representing them, have been more sensitive to the raising of income levels in the fishing community. The decision to introduce a management regime designed to rationalize a fishery is taken by politicians on the basis of their own priorities. Politicians may be more or less cognizant of, and sensitive to, the efficiency arguments for rationalization advanced by economists. They may also be appreciative of the circumstance that resource rents generated through fisheries rationalization are capable of providing the means for income improvement. But many of them, as a first priority, will wish to resolve once and for all the problem of chronically low fishing incomes and thereby remove the importuning pressures that many fishing communities have learned to apply very effectively.

For the reasons indicated, the politician's decision to rationalize the management of a fishery is likely to hinge in whole or in large part on the prospects of income improvement offered by the rationalization scheme. In the industrially advanced western countries where fisheries rationalization is being practiced, it is almost inconceivable that a rationalization scheme would be introduced without substantial support from the fisheries sector involved. That support will be lacking unless the scheme offers a clear promise of improved fishing incomes.

Observant economists involved in fisheries management have acknowledged the reality of the political imperative of income improvement in fisheries rationalization. Thus Moloney and Pearse (1979) have affirmed that "... in all cases we are aware of where governments have intervened to improve the economic performance of fisheries, an important objective has been to raise chronically low incomes of fishermen." They continue with the acknowledgement that "any regime that precludes fishermen from sharing in resource rents is not likely to be acceptable...."

Economists should be cognizant of the intellectual and practical shortcomings of their "efficient" solutions when they rely on simplifying assumptions to overcome the limitations of a welfare-theoretic framework that abstracts from many aspects of income distribution. There can be no unique efficiency solution where optimal factor allocation will be different for each distribution of income [1].

1. This question has been explored in a fisheries context by Bromley and Bishop (1977).

When economists ignore distributional effects in putting forward "solutions" to fisheries rationalization problems, they are advancing a questionable implication of superiority for whatever distribution of income that happens to occur in the scenario they prescribe. This is particularly unsatisfactory in the domain of fisheries, where the prevailing social and political objectives almost always have distinct distributional content. If economic solutions are to be relevant, they must be at least compatible with important distributional objectives, if not actually instrumental in their achievement.

## 3. IMPLEMENTING RATIONALIZATION PROGRAMS

In fisheries rationalization the practical choice generally is between two categories of schemes, limited entry licensing and individual quota allocation. Depending on circumstances, schemes in either category may be made more effective by various supplementary regulations, such as area and time closures, gear and vessel specifications, etc. The relative merits of limited entry and individual quota allocation depend very much on the specific characteristics of the fishery in which application is being considered. Despite some superior features, the individual quota is inherently unsuited for application under conditions characteristic of several fisheries (Copes 1986).

The possibilities of individual quota management of late have drawn much attention. While individual quota schemes have now been introduced in several fisheries, there still are many more limited entry schemes extant. In this paper the effects of transferability will be traced first with an example of limited entry licensing. Subsequently, a discussion will be presented on the consequences of transferability under individual quota management, where these differ from those present under limited entry licensing.

The first major attempt at fisheries rationalization based on the newly developed theories of fisheries economics was introduced in Canada in 1968, expressly "to increase the earning power of British Columbia salmon fishermen and to permit more effective management of the salmon resource by controlling the entry of fishing vessels into the fishery...."[2] A brief review of the structure and operation of the British Columbia salmon fishery rationalization program will serve to illustrate some important problems of rationalization and will help to explain the significance of the issue of license transferability.

The program was based on limited entry licensing (Fraser 1977). Active fishers were "grandfathered" into the fishery, while no further licenses were issued. The existing fleet, however, represented already a greatly excessive fishing capacity in relation to the available catch. In order to shrink the fleet and reduce aggregate operating costs, so that rents could be generated, a "buy-back" plan was included in the rationalization program.

Under the buy-back provision fishermen were offered the assessed value of their vessel plus a bonus for the surrender of their vessel along with its license. By not reissuing the surrendered licenses it was expected that the fleet could be reduced to an optimal size. The buy-back scheme was financed by increased license fees levied on fishing vessels continuing in the fishery. Presumably, owners would be able to pay the higher fees from the benefits accruing to them as a result of increased returns, representing restored resource rents.

## 4. TRANSFERABILITY

When the salmon rationalization program was introduced, the authorities decided to offer vessel owners transferable licenses, meaning that they were allowed to sell their vessel with license attached to any successor at any price they were able to obtain [3]. Licenses were made transferable despite a recommendation in the expert report on which the program was based (S. Sinclair 1960) that non-transferable licenses be used, at least initially. A non-transferable license would be one that a fisherman could not pass on to a successor. It would revert to the management authority after a defined period of time or on retirement from the fishery of the license holder.

2. Press Release. Minister of Fisheries. Ottawa. September 6, 1968.

3 Administratively, licenses were tied to vessels and had to be sold together. To simplify the narrative in the anlysis of this paper, much of the discussion will be couched in terms of the value of the license by itself.

Most economists involved in fisheries management appear to have accepted as self-evident the superiority of transferable over non-transferable fishing rights, be those rights in the form of limited entry licenses or individual quota allocations. Indeed, examples of proposals by economists to use non-transferable rights are scarce[4]. The uncritical acceptance of the purported superiority of transferable rights was succinctly stated in a key article reviewing the main policy alternatives for controlling fishing effort, where Crutchfield (1979 :745) dismissed any consideration of non-transferable rights with the comment : "Even less purpose is served by debate over transferability. Efficiency in use, continuity of operation, and ease of administration are eloquent arguments for relatively free and costless transferability of limited fishing rights."

This ready acceptance of the superiority of transferability seems to rest on an (uncontroversial) estimation that transferability represents an increase in the extent of property rights specification together with a (contestable) corollary that this will allow market forces to bring about a superior factor allocation, leading to an improvement in welfare. There are distinct weaknesses in the assumption of the superiority of transferable rights. First of all, transferable fishing rights do not amount to a full specification of property rights. Each particular system of fishing rights involves an unique set of complementary externalities, the effects of which can not be predicted from the extent of its property rights specification. It may be noted that Johnson and Libecap (1982) have demonstrated the possibility that the introduction of transferable licenses will lead to a reduction in aggregate wealth. What is of greater importance for this paper, however, is the implicit assumption by the proponents of transferability that the distributional effects of rationalization are irrelevant.

As argued above, this assumption conflicts with what is perhaps the most common practical objective of rationalization. What is particularly contradictory, is that many economists explicitly recognize the need for rationalization to raise chronically low fishing incomes, while at the same time advocating transferability of fishing rights as a superior means of rationalization [5]. It is the purpose of this paper to demonstrate the incompatibility of these two positions.

## 5. LICENSE VALUES AND THE EXPECTATIONS TRAP

It is instructive now to explore what happened with the implementation of the British Columbia salmon rationalization program, which had as a major objective the raising of fishing incomes and which operated with transferable licenses. It may be noted that in order to obtain the cooperation of the industry for rationalization, it had been necessary to explain in advance the advantages of the program, including in particular the prospects of much higher returns from the fishery once surplus fishing capacity had been removed by buy-back.

A fortuitous period of good prices and catches confirmed fishers in their high expectations. Obviously, their limited entry license had a substantial value if it offered privileged access to large net returns over and above those prevailing under the previous regime of open access to the fishery. And with their license having been made transferable, vessel owners had the option of collecting a windfall gain by selling it for a substantial amount to an aspiring new fisher tempted by the predictions of generous earnings.

The buy-back authority was constrained by a limited budget drawn from license fees, which was designed to make the buy-back program self-supporting. Soon the authority found that license values had escalated to the point where it was impossible for them to make further purchases of significant numbers of vessels. In consequence, they suspended their operations, at which time vessels responsible for only five percent of the fleet's harvest had been removed by buy-back (Copes 1992), when full rationalization would probably have required half or more of the fleet to be removed. The program had fallen into an "expectations trap". The expectation of large benefits had led to an escalation of license values, which in turn had caused a suspension of the vessel buy-back program on which the generation of increased benefits through rationalization depended. By this process the promise of benefits from the regeneration of resource rents was threatening to become largely a self-defeating prophecy.

As economists should foresee, expected future benefits would be discounted at an appropriate rate and capitalized in the value of a limited entry salmon license. Indeed, the license values that emerged when limited entry was introduced soon

4. Non-transferable licenses have been proposed by S. Sinclair (1960) and by W.F. Sinclair (1978). Copes (1978 and 1980) has argued for non-transferable licenses in direct comparison with transferable license alternatives.
5. A good example is Moloney and Pearse (1979), where the authors advance both of these positions in the same article.

escalated to very substantial sums. License values are known to have fluctuated considerably over the years, though no official data have been collected on license values. Unofficially, license values reaching to over $100,000 for the largest vessels (seiners) were reported in 1984, at a time of relatively depressed conditions in the fishery[6].

The presence of a license value is too easily taken to be an indication of rent that has been capitalized. The continuing presence of license values after implementation of the British Columbia salmon rationalization program has indeed been interpreted as evidence that at least a modicum of success was achieved and that resource rents have been and are being earned in the fishery (Pearse and Wilen 1979). It should be noted, however, that a license value in truth represents *expected future benefits*, not *actual current benefits*, though the latter may have more or less influence on the former. Nevertheless, it is clear that a value may attach to a license even when current fishing operations are yielding no rents or may even be suffering losses.

The estimation by potential buyers and sellers of salmon licences of future benefits to be generated in the salmon fishery is highly speculative, given the many uncertainties involved. The substantial sums that continue to be paid for salmon licenses may in fact rest largely on a dubiously grounded optimism on the part of fishers.

## 6. INPUT STUFFING

A second significant phenomenon that emerged in the salmon fleet soon after limited entry was imposed should now be noted. It appears that the unusually good prices and harvests that were in evidence during the early phases of the limited entry program, generated at least some short term rents. In an attempt to increase their individual shares of the catch and thus of the available rents, vessel operators sought to expand the harvesting capacity of their vessels.

At an early time in the salmon rationalization program regulations had been implemented to prohibit any increase in the net tonnage of replacements for licensed vessels. However, by installing additional and more advanced equipment (i.e., by investing in unconstrained factors), vessel owners succeeded in expanding the harvesting capacities of their vessels. This process has become known as "capital stuffing" (Crutchfield 1979), though it might appropriately be called "input stuffing"[7]. It reduced fleet efficiency on two counts. In the first place it caused a distortion in factor allocation, biased towards unconstrained factors. Secondly, it increased aggregate capacity in the fishery. This meant higher costs for the industry as a whole in relation to the available harvest, resulting in an erosion of rents generated initially by rationalization.

Input stuffing has been strongly in evidence in the British Columbia salmon fishery. Fraser (1977 :52) estimated that real capital inputs in the fishery increased 36 percent over the period 1969-1975, offsetting and greatly exceeding the reduction in capital inputs resulting from the abortive attempt at buy-back. It should be noted, however, that before limited entry was introduced capital inputs in the salmon fishery were already increasing steadily, probably under the influence of a rising trend in real prices for salmon.

Pearse and Wilen (1979) estimated that real capital inputs were growing at an annual average rate of 5.7 percent before 1969, as compared to a rate of 3.7 percent in the period thereafter until 1977. They concluded that while this had eroded much of the potential gain from rationalization, it had not removed all of the gain, so that some resource rent was being generated and reflected in license values.

## 7. THE TRANSITIONAL GAINS TRAP

One further problem area in the salmon rationalization program will now be discussed, namely that of the "transitional gains trap", which has been described by Tullock (1975) in a different context. While this is perhaps the most important of the problems that beset the program, given its objective of income improvement, it is one that has been almost entirely ignored by most analysts.

6. Nonofficial figures obtained from industry sources through the Department of Fisheries and Oceans.
7. Generically, the process might more appropriately be referred to as "factor stuffing" or "input stuffing", as the same effect may be generated in relevant cases by adding to the labor factor through additional inputs of crew members.

As indicated earlier, raising the level of fishing incomes almost invariably is an important objective of rationalization. It has also been an almost universal practice for governments to make the initial distribution of limited entry licenses free of charge to those "grandfathered" in — at least no contrary instance is known to this author. After all, if current fishing incomes are considered inadequate, it would hardly do to place a new and additional charge on fishers before the promised improvement in income was in evidence.

It is clear that the first generation of British Columbia salmon fishers to hold limited entry licenses has been able to benefit therefrom. They have had a double advantage. In the first place, they have been able to share in what limited rents have been generated in the fishery. In the second place, and perhaps more importantly, on retirement from the fishery they have been able to sell at handsome prices the licenses that they acquired at no cost. In respect of this first generation of license holders the objective of improved incomes clearly has been met.

But what about subsequent generations of license holders ? Standard theory suggests that they will have to pay in advance for any benefits (rents) they are expected to derive from the acquisition through purchase of a limited entry license. For the price of their license is the present value of the stream of the anticipated future benefits obtainable from that license. Unless an exogenous change has taken place to increase opportunity cost incomes in the fishery, there is no reason to expect that their net incomes will be improved over the levels previously obtaining in the nonrationalized fishery. If that level of income was considered socially and politically to be too low, then the generations of fishers subsequent to the first license holders will continue to have inadequate incomes.

While there are no studies comparing fishers' incomes in the salmon fishery before 1968 with those of post-first generation fishers after the introduction of limited entry, there is casual empirical evidence of severe financial difficulties suffered by successor generations of fishers. During 1983-1985 about 300 salmon license holders (from a fleet of about 4250 vessels) had their vessels along with their licenses seized by creditors for failure to meet payments on loans taken out to finance purchase of their licensed vessels [8].

The financial strain on fishers undoubtedly was exacerbated by the high value of new vessels affected by input stuffing and by relatively high interest rates. Nevertheless, it seems evident from the extraordinary rate of failure that the net incomes of many successor fishers fell well short of the level needed for viable participation in an industry that was subject to the annual variation in fortunes typical of the salmon fishery.

By providing the benefits of rationalization to the first generation of license holders in the form of transferable rights, the government frustrated its own apparent intention to bring about a lasting improvement of income levels in the fishing industry. The transferable licenses brought on the transitional gains trap. Income improvements that were meant to be lasting, were in fact transitional, i.e. they benefited the first generation of license holders only.

## 8. THE BENEFITS OF NON-TRANSFERABILITY

This section will focus on an analysis of the different scenario that one might have expected had non-transferable, rather than transferable licenses been used in the rationalization of the salmon fishery. The discussion will focus on the differences that would apply in respect of the expectations trap, the input stuffing problem and the transitional gains trap.

A non-transferable license would make it possible to avoid the expectations trap entirely. As fishers retired, their licenses could be withdrawn from the fishery. The number of licensed vessels in the fishery could thus be reduced by attrition to any lower number compatible with the rationalization program. If a faster pace of withdrawal was desired, a supplementary buy-back program could be introduced. As a fisher would not have the option of selling the license to a successor, the premium necessary to induce an offer of the boat for buy-back would be determined only by the net benefits the fisher could expect to reap during the remaining years of fishing before retirement.

One may expect the premium necessary to buy out a fisher approaching retirement to be quite modest by comparison with the premium necessary to buy out a license to which perpetual rights were attached. Clearly, a non-transferable license could make reduction in the number of fishing licenses quite easy. An example may be found in the California abalone

8. Unofficial data obtained from industry via the Department of Fisheries and Oceans.

fishery, where a non-transferable limited entry license scheme succeeded in reducing the number of vessels by attrition from over 500 to about 150, while curbing overfishing and improving incomes in the fishery [9]. Another example is provided by the non-transferable license system in the abalone fishery of the Australian state of Victoria, where the number of divers was reduced by attrition from about 200 to 100 over the period 1968-1979, leaving the industry in an economically healthy condition (Stanistreet 1982).

A non-transferable license will not prevent input stuffing, but is likely to reduce its extent and will make it easier to deal with. Fishers with non-transferable licenses will benefit from input stuffing only in respect of any rents they may thereby capture during their remaining years in the fishery, unless the management authority agreed to compensate them for their investment in stuffing at the time of their retirement. The opportunities for profitable input stuffing may therefore be limited in the case of a non-transferable license.

More significant, perhaps, is the ability of a non-transferable limited license system to offset the capacity-increasing effects of input stuffing, simply by allowing the withdrawal of a few more licensed vessels by attrition. It should also be noted that input stuffing is not necessarily all bad. New technology frequently has features that cut the cost per unit of a vessel's catch. A non-transferable license system may gain advantage in adopting new technology : it may benefit from the cost-reducing aspects of innovation, while avoiding the fleet-level losses associated with capacity-increasing aspects, because it can easily shed surplus capacity as it develops (Copes 1978). In contrast, a transferable license system has proven difficulties in attempting to shed the excess capacity added by input stuffing.

If a permanent improvement in fishing incomes is an important objective, then the avoidance of the transitional gains trap by the non-transferable license is perhaps the greatest advantage that it offers. In treating all generations of fishers equally, allowing no generation to charge its successors for any rents they will earn, the non-transferable license applies a standard of intergenerational equity. If income levels in the fishery need to be raised, the management authority may distribute licenses free or at annual fees that do not fully absorb the rents generated in a rationalized fishery.

## 9. THE INDIVIDUAL QUOTA

It is possible to have either transferable or non-transferable rights in an individual quota regime, with the distinction between the two being much the same as in the case of limited entry licensing. However, the impact of transferability on efforts to reduce harvesting capacity in a fleet is quite different in the two cases. As was demonstrated above, transferability tends to hamper rationalization of effort considerably in the case of limited entry licensing. With individual quota management transferability may serve as a major means of reducing fleet capacity, if such is necessary.

In an individual quota regime (Moloney and Pearse 1979) fishermen are given harvesting entitlements to specific quantities of fish, with the aggregate of the individual quotas in a fishery equalling a total allowable catch determined on the basis of bioeconomic considerations. An initial allocation of these quantitative rights among individual operators in a fishery is likely to be related to historical performance or some other aspect of equity. With quotas divided into small enough units and transferability providing for a free market in these units, rationalization can proceed without any need for further regulatory intervention.

Presumably, in a free market for quota units, the most efficient operators will be able and willing to buy up enough harvesting entitlements from less efficient operators to ensure that the total of their entitlements match the harvesting capacity of their vessels optimally. Less productive operators may remain in the fishery if they wish, but have the option of selling out at the best prices thay can get for their harvesting entitlements, vessels and equipment. It should be noted that those who stay in the fishery, despite low productivity (i.e. small harvests per person-year), should probably not be regarded as "inefficient". If they continue to fish despite small catches, they presumably also have low opportunity costs, making it worth their while to stay.

In the case of the individual quota, transferability also helps to avoid or reduce the input stuffing problem. With an individual transferable quota regime there is no serious need for controls on the number or size of vessels in the fishery, as operators generally have the freedom and the incentive to acquire the most efficient factor combinations. There are

9. Personal communication from E.C. Fullerton, Regional Director of the Southwest Region, U.S. National Marine Fisheries Service.

some circumstances, however, in which an incentive remains for some input stuffing (Copes 1986). This may be the case, for instance, when there are seasonal or spatial concentrations of fish that are particularly profitable to exploit. Operators may then contrive to build in extra harvesting power (distorting optimal factor combinations) to compete more effectively in a race for the most profitable catches.

It is in the area of the transitional gains trap that transferability may remain a serious problem in the case of individual quota management. Of course, it is a problem only if there is a recognized need to provide for a lasting increase in the level of fishing incomes. If that is the case the problem of transferability, generally, is of the same nature and severity as between a limited entry regime and an individual quota regime. With transferability, expected future benefits of rationalization will be capitalized in the trading value of harvesting entitlements. Successor generations of fishers will have to pay for their expected benefits in full in advance and cannot expect to secure any improvement in income levels as a result of rationalization.

## 10. LIMITED-TERM FISHING RIGHTS

An option that needs to be considered seriously in fisheries management is that of issuing limited-term rights, rather than perpetual rights. This is worth considering, whether one is dealing with a limited-entry regime or an individual-quota regime, and whether one is issuing transferable or non-transferable rights. A pervasive feature of the many experiments in fisheries management and rationalization that have been attempted in recent decades is the uncertainty of their outcome and the high probability of new and unforseen problems cropping up. The above account of the attempt at rationalization in the British Columbia salmon fishery serves as a cogent example.

Fisheries managers need to be prepared for "Murphy's Law" : if anything can go wrong with a new fisheries management regime... it will ! The issuing of limited-term rights avoids irrevocable commitments to management systems that may prove both seriously flawed and difficult to undo if perpetual rights have been issued. It provides the opportunity for a fresh start, keeping alternative options open.

Limited-term rights will also help to reduce the effect of the transitional gains trap where these rights have been made transferable. If, for instance, a transferable limited-entry license has been issued for ten years, of which four more years remain, its transfer value will be much reduced by the fact that it offers an entitlement to any future benefits for four years only. At times of reissue there is a fresh opportunity to allocate licenses to successor generation fishers on the same conditions as were enjoyed previously by the first generation of fishers to benefit from a newly implemented limited-access regime. In this fashion most of the enhanced income benefits of rationalization may be spread over successive generations of fishers, serving the purpose of intergenerational equity.

It may be noted that a system of life-time, non-transferable fishing rights also provides a hedge against the contingency of unanticipated difficulties in a new fisheries rationalization program. Rights that are incompatible with changes that need to be made in the management regime may be phased out as fishermen retire. However, a system of limited term rights may be more effective, at least if the maximum term of the rights is reasonably short. In that case there will probably be less delay in phasing out existing rights than in the case of non-transferable rights, where the maximum life-term still running at any one point in time may be quite long.

## 11. CONCLUSION

A question that inevitably suggests itself when non-transferable rights are proposed for the fishing industry is : "Why should rights in the fishing industry be non-transferable when they are not so in other industries ?" Rhetorically, the question may be reversed, suggesting that there may be other industries for which non-transferable rights should be considered. But that is not the topic of this paper, in which the case is being made specifically for the fishing industry – or, as will be explained, for part of the fishing industry only.

If we are looking for reasons to treat the fishing industry differently, we may find it in part in the peculiar nature of a fugitive common property resource. For most fishery resources it is impossible or impractical to contain the resource and

divide it into discrete units to be put under the ownership and control of individual fishing enterprises. Even if fish stocks could be suitably divided amongst enterprises, they could not be separated from their habitats, which form part of a multiple-use marine environmental resource. The government, as custodian of the public marine resource complex, inevitably must assume responsibility for its overall management.

As the discussion in this paper has indicated, the reason for proposing non-transferable fishing rights is to allow for an effective way of dealing simultaneously with the two common policy objectives of fisheries rationalization programs : the generation of resource rents and the permanent raising of the level of fishing incomes. The paper rests therefore on the assumption that there are fishing industry sectors in which incomes are distinctly and chronically low.

To most observers who have been widely involved with fishing matters the casual evidence of low fishing incomes is clear. An analysis of the facts and circumstances behind the assumption has been given elsewhere (Copes 1987). At the same time, it should be emphasized that this paper makes no suggestion that low fishing incomes are universal. In particular, "industrial" fisheries undertaken by corporations typically fall outside the analysis of this paper. The low income problem is more widely present in the small-scale fisheries of individual owner-operators – but these fisheries do accommodate the great majority of fishers.

If by the nature of the fishery governments must assume responsibility for biological and economic management, and if it is acknowledged that there is a serious income problem in the fishery to be remedied, then it appears logical enough that governments should seek to solve the income problem through their management plans. It may therefore be considered a legitimate and responsible undertaking of governments to include as a primary objective in their fisheries rationalization plans, a lasting remedy for chronically low fishing incomes. When they do so and call upon economists to provide them with advice appropriate to this objective, it behooves economists undertaking to provide that advice to consider the implications carefully and craft designs for management regimes that will clearly meet the objective. In that circumstance economists should be careful to set aside any proclivity to work to a more narrow professional agenda that focuses solely or primarily on "efficiency" objectives that are detached from their distributional consequences. The analysis of this paper suggests that in this regard economists, on important occasions, have not served well their patrons in government and have not contributed effectively to the implementation of public policy.

ABSTRACT

*In order to solve difficult management problems, many U.S. Fishery Management Councils are considering Individual Transferable Quotas (ITQs) as a limited access option. Regulation by ITQ offers the potential to control effort without inducing adverse increases in the costs of production. All of the existing ITQ systems are designed to manage fisheries that are dominated by commercial fishing. There is no reason, however, why ITQs should not be considered in recreational or combined commercial/recreational fisheries.*

*The focus of this paper is the south Atlantic king and Spanish mackerel fishery. This fishery is unique in that a large percentage of total annual harvest is landed by the recreational sector. This creates particular problems when dealing with allocation and transferability issues of the ITQ design and additional uncertainty as to ultimate consequences of ITQ implementation. The objective of the study is to consider the potential application of an ITQ to the south Atlantic mackerel fishery, including options for structuring an ITQ system and the constraints of ITQ management in a mixed fishery.*

*Information and data used in this analysis are from the South Atlantic Fisheries Management Council, National Marine Fisheries Service Southeast Regional Office and Fisheries Science Center, and state divisions of natural resources.*

* This paper is based on a report prepared under contract to the National Oceanic and Atmospheric Administration, National Marine Fisheries Service, Silver Spring, MD. The views presented herein are those of the individual authors and do not represent those of their institutions nor of the National Marine Fisheries Service.

## 1. INTRODUCTION

The south Atlantic mackerel fishery[1], like most other fisheries in the U.S., is managed as an open-access resource. Open-access means that anyone is allowed to enter the fishery as long as they comply with basic eligibility requirements. Open-access in the mackerel fishery has led to increased competition between recreational and commercial users of the mackerel stocks and between gear types, geographic areas and full-time and part-time commercial fishermen. Open-access has also led to excess fishing pressure on the stock resulting in the reduction of the benefits from commercial and recreational uses of the stock.

South Atlantic federal and state fishery managers have attempted to ameliorate the negative impacts of open-access by restricting participants' fishing activities (see Milon et al, 1992). User group quotas, bag limits, and gear limitation/prohibitions are all management devices which have been considered as a means to control the level of harvests and reduce competition between users. These management devices have successfully reduced total harvests from the south Atlantic mackerel fishery. However, as in many other fisheries, success has come at the price of inefficient harvesting practices by users of the stock and misallocation of the resource to different user groups. In addition, success in preventing depletion of the stock has encouraged additional fishermen to enter the fishery so that more restrictive management measures are required to maintain the stock.

A potential solution to this problem is an Individual Transferable Quota management system. Individual Transferable Quotas (ITQs) are a means of creating rights in a fishery and limiting the number of participants while meeting biological stock management objectives. Under an ITQ system, fishermen receive "shares" of a fishery stock based on criteria set by fishery managers. Share owners may then harvest as many fish as their share allocation allows using any gear and at any time during the fishing season. This allows the fishermen to make decisions that maximize their return from fishing effort. The stock is protected because the total number of shares issued does not exceed the management's desired harvest level.

Under an ITQ system the efficient utilization of the resource is encouraged through the sale, or transfer, of shares from one ITQ owner to another or to a new entrant into the fishery. Even with the new entrant, however, total fishing effort is limited because the seller of the ITQ shares no longer can harvest that share of the stock. ITQs differ from standard license limitation programs in that the share owner has no incentive to overcapitalize to harvest his/her share of the resource. In addition, ownership of a personal quota reduces the incentive to "race" other fishermen to capture the allowable catch. ITQ systems have been implemented in many fisheries around the world, and recently in the U.S., as a means to limit entry and reduce the inefficiencies of open-access fishing. Muse (1991) provides an overview of these ITQ systems.

The advantage of ITQs are that they create a secure consumptive use, or harvest, right in the fishery and they help allocate the fishery resources to users with the highest value. The consumptive use right is not a complete property right like land ownership. The public still owns the resource and can revoke the right to use the resources. The consumptive use right assures the individual fisherman that his/her share of the resource can be harvested. The harvest right becomes part of the inputs necessary to participate in the fishery so that the fisherman does not view access to the fishery as a free good as with open-access regulation. The harvest right is valuable because right holders can determine their own harvesting practices and scheduling allowing them to obtain maximum value from their share of the resource. If another fisherman offers to buy their right, they can determine whether the sale proceeds are greater than expected future returns from exercising their harvest right. Theoretically this should lead to greater efficiency in utilization of the fishery.

All of the existing ITQ systems are designed to manage fisheries that are dominated by commercial fishing. There is no reason, however, why ITQs could not be used in recreational or combined commercial/recreational (or mixed) fisheries such as the south Atlantic mackerel fishery. As in commercial fisheries, problems of unlimited entry and inefficient allocation to low valued users can be overcome through the transfer of catch rights in the recreational fishery. Theoretically, recreational fishermen who have a high value for the resource could buy catch rights from other recreational fishermen or from commercial fishermen. Similarly commercial fishermen could increase their individual share of total allowable catch by buying catch rights from recreational fishermen. These sales of catch rights could be for part or all of a year or for the duration of the ITQ system. Although each group has a different motive for participating

1. There are two migratory groups of king and Spanish mackerel ; a Gulf of Mexico and an Atlantic Group. This study focuses solely on the potential for ITQ management in the Atlantic Group of the U.S. king and Spanish mackerel fishery.

in the fishery, transfers of shares between different user groups would direct the share of rights to the most valued use. As a result, all harvest shares could be owned by either commercial or recreational fishermen if they are willing to buy the harvest rights. If fishery managers decide that they want to preserve some portion of the total catch for a particular group of users then some of the catch shares can be exempt from trading.

The objective of the following paper is to consider the potential application of an ITQ to a combined commercial/recreational fishery such as the Atlantic Group of the south Atlantic mackerel fishery. In Section 2 the objectives of fishery management under ITQs are outlined. Section 3 describes options for structuring an ITQ system in a mixed fishery. Finally, by way of conclusion, the constraints of ITQ management in a mixed fishery are considered in Section 4.

## 2. OBJECTIVES OF FISHERY MANAGEMENT BY ITQS

### *2.1 Efficiency in Harvesting*

One of the primary objectives of ITQ management is to create economic efficiency. Harvesting under an ITQ system can be more efficient than with traditional approaches due to several factors. First, fishermen are free to choose the most efficient gear and scheduling to harvest their shares so there is no incentive to invest in unnecessary capital and equipment or to fish when market or weather conditions are not favorable. Second, incentives to overharvest are reduced since fishermen own harvest rights that give them a stake in the long-run health of the fishery. Third, commercial harvesters can schedule their effort to provide steady landings during the season thereby making it easier for processors to market the product and avoid short-term gluts. Finally, fishermen are free to choose the level of commitment that they want in the fishery by their purchase of harvest shares. Those that want to be part-time or casual fishermen can hold just a few shares while others who want to specialize full-time in the fishery can purchase as many shares as other share owners are willing to sell.

Efficient harvesting under an ITQ system also implies that Total Allowable Catch (TAC) is allocated to different user groups based on their value for the catch. This means that it is not necessary to continuously decide how much one group of users (such as net fishermen) are allowed to harvest relative to other users (such as hook and line fishermen). As long as individual quota shares are fully transferable, fishermen themselves can determine the highest valued use of the allowable catch.

The above principle also applies to allocations between commercial and recreational fishermen. If charter boat captains want to offer their customers the opportunity to harvest more mackerel than allowed under bag limits, they can buy mackerel ITQ shares. A captain can offer this harvesting opportunity to his/her customers as long as the captain's total catch during the year does not exceed his quota. If he/she wants to increase his/her total catch, he/she could buy more shares from other charter boat captains or from commercial captains. The charter boat captain would be willing to buy mackerel ITQ shares as long as his/her customers are willing to pay for the increased cost of the harvest rights for mackerel. Thus, the recreational charter boat customer determines charter boat captains' willingness to pay for ITQ shares.

The relationship between recreational value and mackerel harvest rights is more direct in the case of the recreational fisherman who wants to personally hold ITQ shares. The recreational fisherman could buy shares from charter boat captains, commercial fishermen, or other recreational fishermen as long as the fisherman is willing to pay the seller's asking price [2].

2. It is not entirely clear that ITQ management will lead to complete efficiency in a mixed commercial/recreational fishery. While similar production and market conditions drive both the commercial and recreational charter/headboat sectors, this may not hold for individual recreational fishermen who, rather than attempting to maximize profit in a standard production theory framework, is interested in maximizing the quality of the fishing experience, catch rate, or time fishing. For example, if under ITQ management stocks increase, it is hypothesized that the willingness to pay for shares will increase in the commercial and charter/headboat sectors. Transfers would occur resulting in shares held by users with the highest value.

### *2.2 Economic Rents*

A second objective of ITQ systems is the creation of economic rents. Open-access regulation leads to excess competition and rent dissipation while ITQ systems limit competition and make it possible for share owners to earn rents. Whether these rents should accrue to the ITQ share owners or to the public through the federal government is a matter of public policy.

If it is decided that rents should accrue to the public, there are several ways that this can occur, each with differing implications for commercial and recreational classes of fishermen. First, the initial allocation of shares can be by public auction whereby each share owner pays for the harvest right. The amount each bidder would be willing to pay to own shares is a measure of their expected rents from owning the shares. In this case, commercial and recreational fishermen would be treated equally since they would express their personal value for a share of the total catch. Since shares would be allocated to the highest bidders, the public would collect the full expected rents under the ITQ system. These rents would not be collected if shares are allocated by a lottery or are given to fishermen. This type of auction system is currently used by the federal government for mineral mining and timber harvesting rights but has not been used for fisheries due to restrictions in the Magnuson Act.

A second way rents can be collected by the public is through income taxation. Profits earned by commercial fishermen or charter boat operators under an ITQ system could be taxed at prevailing individual or corporate tax rates. This allows the federal government to recover part of the ITQ rents. If ITQ shares are treated as productive assets like stocks, bonds and other property, part of the rents would be taxed as capital gains when ITQ shares are sold. However, individual recreational fishermen who own ITQ shares would not be taxed since these rents accrue directly to the individual. These rents would not accrue as income but would be capitalized in the market value of the ITQ shares. Part of these rents would be taxed when the ITQ shares are sold if recreational shares are also treated as productive assets.

Another way ITQ rents could be taxed is with a flat tax per unit of fish harvested or per share owned. The disadvantage of the per share approach is that rents are not uniform across share owners so the tax may over-tax some share owners and under-tax others. Alternatively, a tax on fish harvested creates an incentive to under-report actual landings. This would be especially true in the case of recreational fishermen who might have increased incentive to high-grade. This approach generally would make it more difficult for fishery managers to monitor the stock. As a practical matter, the flat tax per share would be less harmful since it does not encourage cheating and could be imposed as part of annual permit fees.

### *2.3 Stock and Environmental Considerations*

A third objective of ITQ management is to maintain consistency with biological and environmental objectives such as species conservation and maintenance of critical habitat.

Concern for stock levels under ITQs is no different than biological concerns under traditional fisheries management based on TAC. It is important to note, however, that unlike traditional fisheries management an ITQ system creates incentives for share owners to comply with TAC and consider stock conservation explicitly. Since the value of ITQ shares is based on expected harvest in the future, over-harvesting that jeopardizes future harvest can only reduce the value of shares. Although a single fisherman, either commercial or recreational, may still perceive some advantage to quota-busting, other share owners have a proprietary incentive to insure that this does not happen [3].

In addition to target species conservation, it is hypothesized that the ITQ mechanism will lead to a reduction in gear on the fishing grounds. The removal of redundant gear will subsequently lead to a reduction in habitat degradation and by-catch. Other environmental objectives related to specific gears can also be addressed in ITQ management. For example, if a specific gear causes excessive by-catch of other species or degrades important spawning habitat, it can be prohibited from use under an ITQ system. As long as fishermen can select from other gears and determine their own scheduling and harvesting rates, the ITQ system will encourage more efficient harvesting while realizing environmental objectives.

---

In the case of a small-scale recreational fisherman, however, though he/she may perceive an increase in the quality of their fishing experience as a result of increased stock size, he/she may be constrained by gear type or fishing range. In this case the benefits of the increased stocks will not be realized and incentives to trade over the long run diminished.

3. Compliance incentives are particularly strengthen if the initial ITQ share allocation is denominated in terms of a percentage of TAC.

## 3. OPTIONS FOR STRUCTURING AN ITQ SYSTEM FOR THE MACKEREL FISHERY

### *3.1 Scope of Quota Share Ownership*

An ITQ system can be designed to operate for one group of fishermen within a fishery or across all fishermen. Trading and transferability of shares would be determined by the number of share classes and the rules governing conversion from one class to another. In the context of a joint commercial/recreational fishery this means that ITQs can be created for :

(i) the commercial fishery only with recreational harvest regulated through bag limits and season closures ;

(ii) a single class of ITQ shares for both commercial and recreational sectors with no restrictions on transfers between commercial and recreational fishermen ; or

(iii) two separate classes of ITQ shares - one for the commercial sector and one for the recreational sector.

While the administrative and enforcement costs of the first option would be relatively low given the small number of commercial participants involved, transferability of ITQ shares would be limited and there would be no control on entry into the recreational fishery. Option 2 would provide the maximum amount of transferability among fishermen and promote efficient allocation. However, administrative and enforcement costs could be high given the large number of recreational fishermen involved. In addition, recreational fishermen may object to ITQ reporting requirements for small quantities of fish, while commercial fishermen and processors may object to the market uncertainty caused by highly variable supplies from ITQ owners.

The third option is the most desirable from an efficiency point of view as it provides for a high degree of ITQ share transferability yet allows part of the recreational sector catch to be regulated by bag limit/seasonal closures. Commercial shares could be transferred and/or converted to recreational shares, or vice-versa, at specific times such as the first month of the fishing year. The total shares allocated as commercial ITQs, recreational ITQs, and recreational bag limit shares would never exceed 100 percent of the TAC. This system would promote efficient allocation between users while helping to reduce administrative and enforcement costs. Retaining bag limits for part of the recreational sector catch would eliminate direct reporting for anglers who only want to keep their bag limit thus reducing enforcement costs. Recreational fishermen who want to keep more than the bag limit could purchase ITQ shares and harvest their shares according to regulations governing recreational harvest.

### *3.2 Commercial Share Classifications*

There are many ways that ITQ shares could be subdivided within a general commercial classification. For example, separate subgroups (by gear type and/or vessel size) of ITQ shares within the commercial class could be created with restrictions on transfers to trading within each subgroup. Alternatively, subgroup classifications within the commercial sector could be used in the establishment of the initial allocation of ITQ shares with full transferability between the subgroups allowed once the system is operational. It is necessary in either case to include classes of shares that confer with the different motives for using the fishery.

While subgroup share classifications and restricted transferability may have social or political justification, these features of commercial shares would limit the potential efficiency gains that could be expected from an ITQ system. If the Council wishes to consider the interests of certain groups of commercial fishermen, it is argued that these concerns should be addressed only in the initial allocation. If a certain subgroup receives quota shares, they should be free to decide whether they want to continue fishing or to sell out to other fishermen. In either case the individual fisherman makes the choice and is not dependent on decisions of the Council beyond the initial allocation.

### *3.3 Recreational Share Classifications*

In addition to subgroups within a commercial class of ITQ shares, it may also be desirable to create subgroups within a recreational share class. This would extend beyond the basic distinction between recreational ITQ share fishing and bag limit fishing discussed earlier. Separate subgroups within a recreational share class for certain groups of recreational

fishermen such as charter boats, party boats or other identified recreational groups could be established. The rationale for these subgroups would be similar to that for the commercial subgroups : to protect certain recreational groups such as charter boats or to protect stocks in specific areas. Subgroups may also be useful if the costs of enforcement differ between recreational groups. Alternatively, the initial allocation of ITQ shares could be used to address specific distributional concerns about recreational share ownership and allow full transferability to determine the most desirable pattern of share ownership.

While it may be desirable to create subgroups of ITQ shares for certain recreational groups where the costs of enforcement are lower, such as for charter or party boats, the creation of the subgroup shares with restricted transferability essentially "locks-up" a share of the resource for a particular group with no consideration of whether the resource is being allocated to its highest valued use. This could perpetuate inefficient use of the resource since other groups that might have a higher value for that share of the resources could not purchase the harvest rights. One way to avoid locking-up shares of the resource, while still recognizing certain recreational subgroups is to use the initial allocation to give shares to these subgroups and then allow all other users to decide if they want to buy-out the share owner's rights. Full transferability with other recreational harvesters or with commercial harvesters allows the users to continuously determine the best allocation of the stocks rather than relying on the Council to make these decisions.

### *3.4 Total Allowable Catch and ITQ Management Units*

Both king and Spanish mackerel are jointly managed by the South Atlantic and Gulf of Mexico Fishery Management Councils under a TAC limitation (see Milon et al, 1992). Each species and migratory group has a TAC. Annual TACs are defined to account for population changes and/or management objectives. An ITQ system would divide annual TAC into individual shares. The initial share allocation would be denominated in specific units such as pounds or number of fish or as a percentage of TAC. The latter approach is preferable since allocating a specific quantity of fish may cause problems if TAC is revised upward or downward in the future. Shares defined in terms of percentages of TAC could be converted to specific individual catch allocations, or quotas, as TACs are revised over time. The percentage shares approach does introduce some uncertainty about the actual amount of catch allowed by an individual fisherman, but this is necessary to reflect the biological variability of the stock and possible changes in the Council's objectives for the stock. Percentage shares of TAC could be denominated in terms of the total weight of fish that could be harvested under an individual quota or in terms of the total number of fish that could be harvested under an individual quota.

Since TAC can be specified as either total weight (pounds) or total number of fish harvested, the choice between options depends on how the catch measurement unit influences incentives to utilize the fishery resources and the costs of monitoring individual catch. Individual quota defined in terms of weight would encourage commercial fishermen to land all of their catch since there is little price variation for mackerel of different weights. If commercial individual quotas were denominated in terms of numbers, there would be an incentive to discard smaller, less valuable fish. Excessive high-grading would jeopardize the Council's stock management objectives.

On the other hand, denominating recreational individual quota in terms of weight makes it more difficult to monitor recreational catch and enforce quotas and bag limits. Since most recreational catch is likely to be less than 100 pounds per trip, it would be difficult to measure the weight of each catch and monitor quota. Therefore, it is more appropriate to denominate recreational individual quota in terms of number of fish.

An alternative is to initially denominate all shares in terms if weight. If the share is used as a commercial class ITQ share, the shareholder's allocation would be given in units of weight (e.g. 1000 pounds of mackerel). If the share is used as a recreational class ITQ share, the share holder's allocation would be converted to a specific number of fish based on conversion ratio set by the Council (e.g. 100 pounds of mackerel = 10 fish). Similarly, shares set aside for recreational catch under the bag limit would be converted from weight to numbers using the same conversion ratio. This is the procedure that is used under the current south Atlantic mackerel TAC allocation system.

### *3.5 Initial Allocation of ITQ Shares*

The initial allocation of shares depends, in part, on the classes of shares created for the ITQ system and the relative importance given to fairness and historical participation considerations suggested in the Magnuson Act. The initial

allocation of ITQ shares is important because it establishes which groups will have quota shares to use and/or transfer. It would be possible for the Council to : (1) create one class of shares and leave the allocation decision to a lottery or auction (The lottery or auction could be open to anyone who wishes to participate or it could be limited to individuals who meet specific eligibility criteria.) ; (2) allocate ITQ shares to individuals based on historical participation as determined by average catch records and/or some other indicator during some prior specified time period ; or (3) allocate ITQ shares according to different criteria for each class of shares created. In the latter instance, commercial shares could be allocated based on historical catch records or some other historical participation indicator while recreational shares could be allocated via a lottery after some portion of the TAC is assigned to recreational bag limit fishing.

The first option would make it possible for anyone to be allocated ITQ shares if they were lucky enough to win them in a lottery or to purchase them in an open auction. This option is appealing from a fiscal point of view because it provides the Federal government with a means to collect the rents that would accrue to ITQ share recipients through a lottery. The primary short coming is that the Magnuson Act does not currently authorize auctions [4].

The second option is desirable if only commercial ITQ shares are created. Since most recreational fishermen do not have historical catch records to document participation, there would be no way to allocate recreational shares. Thus, any trading of ITQ shares could only involve commercial ITQ shares which may not be convertible into recreational shares. The advantage of the third option is that it allows the historical participation criteria to be used to initially allocate commercial ITQ shares and provides a method to allocate recreational ITQ shares. The recreational allocation could be used to create tradable ITQ shares within the recreational sector depending on the extent of the Council's interest in promoting recreational sector trading. The lottery is a simple way for the Federal government to fairly and equitably allocate ITQ shares to the recreational sector while maintaining consistency with the current Magnuson Act.

### *3.6 Initial Eligibility Criteria*

The eligibility criteria for the initial allocation of ITQ shares depends on the types of ITQ shares created and the initial allocation mechanisms. ITQ share ownership could be made open to anyone regardless of the class of shares a fisherman wanted to obtain or based on specific eligibility criteria for each class of ITQ shares to reflect certain Council priorities for ITQ share ownership. Criteria based on demonstrated participation in the fishery will tend to limit the number of fishermen eligible for initial ITQ share allocations but these criteria would reward fishermen who have been most active in the fishery. On the other hand, if eligibility was open to anyone who wished to receive ITQ shares there would be considerable opportunities for share trading. But, fishermen who have actively participated in the past may have to give up part of their historical catch to accommodate new entrants. Open eligibility may also make ITQ shares so small that it would not be economical for an individual to hold an ITQ share and comply with permitting and reporting requirements.

While the first option would make it easy for anyone who wished to own ITQ shares to participate and would allow ownership of multiple classes by a single fisherman, it creates the possibility of speculation by individuals who do not wish to participate in the fishery but want to receive an ITQ share allocation for future sale. Ownership of multiple classes of ITQ shares may also make enforcement more difficult since each class of shares may have different reporting requirements.

The second option, on the other hand, gives the Council the latitude to identify certain priorities for initial ITQ ownership to facilitate the success of the ITQ system. For example, the Council may decide that commercial ITQ shares should be allocated to long-time mackerel fishery permit holders with certifiable catch records and no history of permit violations. Similarly, recreational ITQ shares may be allocated to long-time charter vessel permit holders with no record of violations. The Council may also decide that individual fishermen should not hold more than one class of ITQ shares so that a fisherman who held both commercial and charter permits would only be eligible for one class of shares. This would aid in enforcement since each class of shares could be monitored under a separate system of reporting.

4. It is clear that in the context of a joint commercial/recreational fishery any lottery process (if it were authorized) must include protocol unique to the mixed nature of the fishery. For example, in the south Atlantic mackerel fishery there are more recreational than commercial participants. Therefore, if the intention of the Council is to provide for an equitable allocation, the lottery must include some weighting mechanism that adjusts for this imbalance.

### *3.7 Duration of Rights*

The duration of ITQ ownership rights is an important issue because it influences the relative value of share ownership. The duration of the ITQ ownership of shares could be limited to a short period of time such as 1 or 2 years to determine whether the system is workable and the Council's desired share allocations continue to exist or defined as indefinite pending subsequent amendment. In the latter case, the market for share transfers is left to determine whether the system is working and the allocation of shares correct.

While it could be argued that limiting the duration of ITQ rights gives fishery managers more flexibility to adjust share allocations or to terminate the system if desired, the first option would create considerable uncertainty about the future status of the ITQ system and discourage investment in share ownership. Uncertainty about the Council's future intentions could undermine the ITQ system and cause it to fail. While the Council would have some flexibility to redefine and reallocate rights, it is not clear that the ITQ system would accomplish much more than the current management system and would tend to perpetuate current problems. The second option, on the other hand, would be more likely to encourage share investment and trading. The market for shares both within and across shares classes could help to allocate mackerel stocks to the users with the highest value and eliminate the need for the Council to reallocate harvest rights. The Council would always have the option of eliminating the ITQ system by amendment if they perceived that management objectives were not being met.

### *3.8 Permit Requirements*

Under a joint commercial/recreational ITQ system a fisherman could not legally harvest mackerel unless he/she held ITQ shares or he/she fished under the bag limit. As in any ITQ there will always be some incentive to cheat by fishing without ITQ shares or by trying to harvest more than the quota owned by the fisherman (quota-busting). Therefore, it may be desirable to require fishermen to possess individual permits. Permitting could include a general purpose permit to fish with ITQ shares regardless of the class of shares owned or a special permit for each class of ITQ shares with an exemption for recreational fishing under the bag limit. Under the second option, permits would be issued for each type of ITQ share to help distinguish those who are fishing for the purpose of selling their catch from those who wish to keep fish solely for their own use.

The first option would impose some costs on ITQ participants but would help to overcome incentives to cheat under the ITQ system. Each share owner, regardless of the class of shares owned, would be required to possess an annual permit that would allow the owner to harvest his/her shares during the fishing year. New buyers or lessors of ITQ shares would also have to possess a permit. Penalties could then be tied to permit renewal since the Council could deny permits to anyone found in violation of ITQ system operating procedures. The main shortcoming of this option is that it is not tied to specific classes of ITQ shares.

The second option would help to reinforce a system of separate classes of ITQ shares. Fishermen who wished to use their ITQ shares for commercial purposes could be required to have a "harvest and sale permit" that would allow them to sell their catch to licensed dealers. Those who wished to use their ITQ shares for recreational purposes could be required to have a "harvest and possession permit" to allow them to keep their catch. Penalties could be imposed for selling catch under a possession permit. This sharp distinction between commercial and recreational harvesters of mackerel may be necessary due to the potentially high costs of monitoring recreational catch. A "no sale" condition on recreational ITQ quotas would minimize incentives to exceed quota. The enforcement effects of dual permits could be reinforced by making it illegal to possess both harvest/sale and harvest/possession permits concurrently. The two types of permits would make it easier to monitor individual quotas since each type of permit could require different reporting mechanisms (see *Reporting Requirements* below). This dual permitting approach may be necessary because most states in the south Atlantic region do not have a fish sale reporting system to monitor individual fishermen sales. Penalties for violating permit restrictions could be tied to annual permit renewal. NOAA general counsel could then penalize violators who have reduced their exposure to enforcement by leasing shares to associates. Recreational fishermen who fished under the bag limit would not be required to have a permit since their catch is restricted by the bag limit. This would help to reduce the administrative and compliance costs for the ITQ system.

*3.9 Reporting Requirements*

The benefits from ITQ management depend, in large measure, on effective monitoring and enforcement. This means that a system to track and monitor individual quota harvests is a necessary first step. The design of this catch monitoring system should take into account differences between commercial and recreational catch and the broad geographic dispersion of mackerel harvesting activities in order to reduce monitoring and enforcement costs. A reporting system could be based on catch "coupons" or an electronic "credit card" required for all ITQ share holders including all recreational fishermen. Alternatively, a separate system of individual catch reporting could be required for commercial and recreational ITQ share holders with recreational fishing under the bag limit monitored by the existing Marine Recreational Fishing Survey.

While the first option provides a feasible means of monitoring individual catch for commercial harvesters, it is likely to be costly and difficult to administer for recreational harvesting. Given the large number of landing ports along the south Atlantic coast it is unlikely that enough agents could be designated to make the system effective. In addition, many recreational fishermen may find the system burdensome and decide not to comply. The second option, on the other hand, tailors the reporting system to the unique aspects of each user group. Individual commercial quotas could be monitored with a coupon and "double-entry" system. The double-entry system could consist of designated agents (fish houses, marinas, etc) who collect coupons equivalent to landings under each quota and file reports on quota landings with the National Marine Fisheries Service. A similar system could be set-up with an electric credit card that would track each individual quota account through a computer network.

Recreational fishermen who hold ITQ shares could be issued non-reusable tags in conjunction with a harvest and possession permit. The tags issued would be equivalent to the number of fish the share holder was entitled to for the share held and the Council's weight-number conversion ratio. All mackerel landed by a recreational fishermen holding ITQ shares must be tagged. Recreational ITQ share owners could also be required to keep a logbook of mackerel catch and return used tags to the National Marine Fisheries Service. The share holder's quota would be filled when the tags are exhausted. Penalties could be imposed for fish landed without tags. Recreational fishermen who do not own ITQ shares would not be required to tag their fish as long as they complied with the bag limits. Total catch by recreational fishermen fishing under the bag limits would be monitored with the Marine Recreational Fishing Survey as it is now done. Recreational ITQ share owners may attempt to harvest their mackerel quota quickly and then land mackerel under the bag limit until the season closes. It may be necessary to prohibit such actions. Restricting recreational ITQ share owners would reduce uncertainty about the number of fishermen fishing under the bag limit and make it easier to set bag limits to keep the season open as long as possible. This approach to reporting recreational ITQ catch would reduce the administrative cost of the ITQ system and help to provide better data on mackerel harvests than with the current system.

*3.10 Gear Restrictions*

A majority of king mackerel landed commercially in the south Atlantic is harvested by hook and line, while Spanish mackerel is primarily harvested by gill net. The recreational fishery is almost one hundred percent hook and line. It is assumed that under an ITQ, Councils would continue to regulate against gear types which result in undesirable side-effects to the environment (such as by-catch by drift nets). However, one of the goals of an ITQ is to promote efficiency of harvest and production. Therefore, it is necessary to consider carefully whether a fishery should be allowed to operate under no gear restrictions or whether the benefits (both environmental and economic) outweigh the costs of regulation. Options for gear restriction in the south Atlantic mackerel fishery include : (1) no gear restrictions on commercial or recreational harvest ; (2) all gear approved by the South Atlantic Fisheries Management Council would be allowed ; or (3) all approved gear would be allowed for the commercial harvest of king and Spanish mackerel under the ITQ system while recreational harvest would be restricted to hook and line.

The first option is clearly questionable under the Magnuson Act which emphasizes a policy of fish resource conservation and protection of related habitat. The second option would allow fishermen freedom to choose cost minimizing, efficient gear types to harvest their quota. This is desirable unless there is some concern that certain gear types could lead to individual catches that could significantly exceed individual quotas. In addition, the possibility that recreational harvests may exceed allowable catch is raised. Recreational use of gillnets or seines, for example, could lead to catches in excess of the quota or the bag limit and potential problems of high-grading, illegal discards, and increased fish mortality rates. The third option would allow any gear approved by the Council to be used to harvest mackerel under a harvest/sale permit. This would lead theoretically to cost minimizing behavior by commercial fishermen and uphold the

environmental and conservation objectives of the Magnuson Act. Recreational fishermen fishing for mackerel under a harvest/possession permit or the daily bag limit could be limited to hook and line. This gear restriction could decrease the mortality rate for mackerel released after catch.

### *3.11 Penalties*

Because the benefits obtained from any ITQ management scheme depend on compliance with individual quotas, gross violations (such as commercial quota busting, harvesting above the bag limit, or failure to report landings) warrant strict penalties. Experience suggests that exceeding individual quotas or "quota busting" has been one of the most frequent problems with ITQ systems. Quotas are exceeded by either not canceling coupons, not turning in tags so that they can be used again, or fraudulent use of coupons. An ITQ system is not likely to succeed if individuals can exceed their quotas without a reasonable probability of detection, or without severe penalties when violations are detected. Because quota share ownership involves a type of long term investment on the part of the fishermen, individuals may be more willing to report violations they observe than under traditional open access fishing. In order to address this issue infractions such as quota busting, non-reporting or fraudulent use of coupons or tags could be penalized with temporary permit sanctions. Alternatively, infractions could be penalized by forfeiture of ITQ shares and harvest/sale or harvest/possession permit sanctions.

Under the first option the National Marine Fisheries Service could only revoke a share owner's permit to penalize non-compliance with ITQ rules. Given that permits would be obtained on an annual basis, this temporary sanction would have little long term impact on developing incentives to comply. The second option allows for penalties for non-compliance to include both forfeiture or sanction of annual harvest/sale or harvest/possession permits, as well as ITQ share holdings within a given year. In this case NOAA general counsel would have two effective means of penalizing violators. The individual who has reduced his "exposure" by dividing total shares among family members can be sanctioned and kept from fishing by removing or suspending their permit.

Neither of these two options address the problem of fishermen harvesting without ITQ shares in excess of the bag limit. Undoubtedly some fishermen will attempt to catch more mackerel than legally allowed without owning ITQ shares. Under the catch reporting system described above, this illegal catch could not be sold legally because fish houses would be required to buy mackerel only from ITQ share owners with harvest/sale permits and they would be required to report all mackerel purchases. It is possible, however, for "black market" sales to occur directly off a boat to an unauthorized buyer. To make ITQ share ownership meaningful, it will be necessary to have sufficient policing to assure that illegal catch does not become a significant part of total harvest. These violations of the ITQ system would need to be sanctioned under general enforcement provisions of federal fishery law. It should be recognized, however, that the geographic distribution of the mackerel fishery may make it very expensive for the National Marine Fisheries Service to provide sufficient policing of illegal catch.

### *3.12 Transferability*

Transferability is of paramount importance in an ITQ system of management. Theoretically, transfer of allocated shares, or the sale or lease of individual quota, allows for greater efficiency in utilization of the fishery. Transferability includes the sale of percentage shares and the sale or lease of all, or a fraction of, individual quota. Sale or lease of individual quota could be accomplished by selling or leasing individual quota coupons for the quantity of mackerel denominated by the face value of the coupons. The Council could allow percentage shares to be sold to anyone within a share class, whether they hold a percentage share or not, during any part of the fishing year, but require that the sale or lease of individual quota be to share holders only. Alternatively, the sale or lease of percentage shares and individual quota could be open to anyone within a share class whether they hold a percentage share or not.

Restricting the sale of individual quota to vested share holders might increase incentives for compliance and simplify monitoring and enforcement of the ITQ program. However, limiting the quota transfers to share holders would restrict the ability of new entrants to enter the fishery during the fishing year and thereby limit fishermen's responses to seasonal variations.

The second option, on the other hand, would allow for the free movement of quota during the fishing year within all share classes. Unrestricted transfer within each share class lets the market work unimpeded. The potential for quota busting and non-reporting of catch is increased if all entrants can exceed quota during the year. However, the monitoring and enforcement associated with the permitting process should help to minimize these problems.

### *3.13 Convertibility*

Convertibility is an element that is unique to an ITQ system involving both recreational and commercial classes of share owners. Convertibility between commercial and recreational shares can be allowed to occur at any time during the fishing year or be restricted to the time of permit renewal during the first month of the year fishing year. The choice depends on the potential for market instability and enforcement problems with unrestricted conversions.

Allowing conversion at any time of year would provide maximum flexibility in the movement of quota shares between users. However, it may result in erratic movement into and out of the commercial fishery and increased uncertainty related to harvest and price expectations. It could also lead to strategic behavior as recreational fishermen try to buy commercial quota to sell fish they caught in excess of the bag limit.

Limiting conversions to the time of permit renewal during the first month of the fishing year would help to stabilize the commercial and recreational markets for shares/quota during the fishing year and reduce the administrative costs of the system. This may lead to some misallocation since harvest rights cannot flow to the highest valued use during the season. But this will be only temporary and would not likely offset the benefits of greater stability in the ITQ share/quota markets. To minimize the costs of enforcing quotas and sale restrictions under a harvest/possession permit, it may be desirable to restrict a share owner from holding both harvest/sale and harvest/possession permits concurrently.

## 4. CONCLUSIONS

While theoretically an ITQ system will lead to more efficient harvesting and allocation of fishery stocks than traditional management systems, limitations associated with individual fisheries may hinder their success. In the south Atlantic mackerel fishery the conflict between commercial and recreational fishermen may automatically present problems for the successful implementation of an ITQ system. That is, if in fact the ITQ system includes both classes of recreational and commercial fishermen, trading between the groups must occur in order that shares are transferred to individuals with the highest value. Political interests may impede such transferability.

In addition, the success of an ITQ in the mackerel fishery (as in many other fisheries) may be limited if the administrative and enforcement costs of the system outweigh efficiency gains. The creation of ITQ shares requires an administrative system to record share ownership and transfers, issue annual harvest share quotas and permits, monitor compliance with share quotas, and enforce quota limits and other restrictions. Costs are also imposed on participants in the fishery since they must establish a personal recording system to assure compliance with their individual quotas, bargain with other fishermen over the sale or purchase of ITQ shares, and pay any administrative/legal expenses resulting from disputes under the system. Aside from enforcement costs required to monitor harvesting under traditional management system, most of these costs are unique to an ITQ system.

There are few rules that can be used to predict whether administrative and enforcement costs will exceed efficiency gains from an ITQ system. However, one general principle is that administrative and enforcement costs will be higher in fisheries that are dispersed over a wide geographic area with a larger number of participants and many landing sites. Unfortunately this is the situation in the mackerel fishery where harvesting occurs over the full south Atlantic region and in the Gulf of Mexico by a relatively large number of commercial and recreational fishermen. Given the migratory nature of mackerel, it is unlikely that ITQ shares would ever become concentrated in the hands of a few fishermen who would harvest the TAC from within a small geographic area.

The physical characteristics of the mackerel fishery (Sutter et al, 1990) suggest that the possible success of an ITQ system will depend heavily on the administrative and enforcement costs required to implement the system. Therefore, it will be important to design a system that reduces these costs as much as possible while achieving the objectives of ITQ management. This can be accomplished in the mackerel fishery by careful attention to the administrative and enforcement costs implied by different ITQ systems structure and operating requirements as cited in this paper.

Another constraint in developing an ITQ system for the south Atlantic mackerel fishery is the fact that mackerel are not regulated solely by the South Atlantic Fishery Management Council. The Coastal Migratory Pelagic Fishery Management Plan is administered jointly by both the South Atlantic, Gulf of Mexico and the Mid-Atlantic Councils. This coordination is necessary to manage the two separate migratory groups of king and Spanish mackerel. In addition, mackerel harvesting is not confined to the Federal Exclusive Economic Zone. Although there are no reliable statistics to document the percentage of catch from non-federal waters, it is an accepted fact that mackerel are frequently caught in state waters. As discussed previously, this has not been a major problem since most states in the south Atlantic and Gulf of Mexico regions have in the past coordinated their management efforts with the Coastal Migratory Pelagic Fishery Management Plan. However, Florida has argued for and adopted different catch regulations to address problems unique to mackerel fishing in that state. Since fishermen in Florida currently account for a major portion of the total mackerel harvest, it is clear that this unique problem, as well as those mentioned above, cannot be ignored if the objectives of a successful ITQ program are to be achieved.

# From Open Access to Communal Property : the Case of the Fishing Community in Muxía.

**Antonio García Allut**

University of La Coruña, Dept of Anthropology, Campus da Zapateira s/n, 15071 A Coruña, Spain

ABSTRACT

*The analytical model predicts the eventual over-exploitation of all common resources, attributing the causes of this degradation to the uncontrolled and maximalist conduct of the producer. Nevertheless, angles of this type are contradicted by the surprising number of cases where the producers have been able to restrict access to the resources and to establish rules among themselves concerning their use without the need for state intervention.*

*In this paper, we will present an example of how the fishing community of Muxía, Galicia (Spain) has modified the rights of the fishing community from certain common resources with open access to convert them into communal property rights, where both access and the resources themselves are controlled by the group of fishermen belonging to this community through the (informal) setting-up of a co-operative system of exploitation known as "A Compañía" (The Company).*

## 1. INTRODUCTION

This type of analysis draws attention to the fluctuations brought about in fish stocks once the exploitation begins. For those in defence of this model, the differences in the fish quantities beforehand (in their original state) and after the exploitation (diminishing to critical levels) represent the starting point in the developing of an approach, as far as the economic behaviour of the producer in relation to the open-access method of exploitation, is concerned.

According to this, the producer will operate on the fishing resources in an indiscriminate way, his only object being to obtain the maximum profit in the minimum time (Gordon, 1954 ; Scott, 1955), being unaware of the fact that fishing territories can only withstand, due to the finite nature of the resoures, a finite amount of exploitation (Hardin, 1968). From this point of view, uncontrolled, maximalist production behaviour, will not lead to anything else but ruin. In conclusion when the resources are granted for common use and exploited under a survival of the fittest régime, the Tragedy of the

Commons situation is brought about (degradation of nature). Only through state intervention or privatization of the resources can this free competition be curbed and over-exploitation avoided (Gordon, 1954 ; Hardin, G., 1978,1989). However this type of analytical approach, while giving more importance to the biological factors (equilibrium in ecosystems) and economics (stocks) than to the social factors themselves, that is to say, the people and the relationship between the social groups (Breton, 1987), interprets the fisherman as a individualistic predator. They do not take into consideration that the producer is subject to certain norms which are no more than ways of negotiating the common resources, they are territorial control processes linked as much as to access as to exploitation.

Therefore the fishermen are able to develop their own exclusive control and self-regulation (McCay, 1987), creating in fact territorial behaviour (economically defensible) where the costs of using and defending an area are inferior to the benefits. They are able to modify, once and for all free access to the resources, converting the common property use, "That which belongs to everyone and at the same time no-one" into exclusive use for a few.

According to McCay & Acheson (1987 :9) the impoverishment of the resources and the communities which depend on them, is closely related to the demands of capitalism, watering down the causes which motivate the tragedy by putting more emphasis on the milieu than on the free behaviour of the producer. On the other hand, the Theory of the Commons finds support in the individualism of the fisherman and the absence of the institutional control which regulates fisheries, deducting importance from the socioeconomic milieu and the regulatory mechanisms which interact in the granting of common property use. The error which Hardin made and which conditioned his complete analisis was identifing the open-access rights with those of common property use, forgetting the existence of certain non-governmental forms of controlling access and appropriation of resources, through the establishment of norms orientated towards regulating the negotiating rights.

Our interest lies in showing how this procces was "constructed", outlining the particular factors which intervened in the process and favoured the birth of an exploitation system in the régime of communal property use. The creation of "A Compañía" as the cornerstone upon which the exploitation is organized, is the gelling and cohesive element which will facilitate success.

## 2. THE ECOLOGICAL AND SOCIOECONOMIC ENVIRONMENT OF THE MUNICIPALITY AND COMMUNITY OF MUXÍA

This costal municipality situated in the far northwest of Galicia (Norwest of the Iberian Peninsula), pertains to the province of La Coruña. The municipality has 6,411 inhabitants distributed throughout a 120 square km., area, who live in small population groups ("aldeas"), spread out in the interior of the territory.

In Muxía, a village with a urban structure, there are 1,676 inhabitants of which 314 are dedicated to fishing.

The village is situated in the lowest area of a rocky headland which juts into the ocean ("Itsmo da Barca"), orientated to the north towards the Camariñas Ria.

In 1980 a harbour was built to give shelter to all the boats of the village. It also possesses a fish market administered by the town council, and since 1988 an ice factory, which is the property of the Association of Fishermen "Cofradía de Pescadores Virxen da Barca".

An economic envoirnment, generally showing a deficit, is going to reduce the prospect and opportunities of alternative employment in other sectors, leaving its inhabitants with the fishing industry as the main fallback to strengthen their economies. The service and commercial sector industry ( 11 shops, municipal administration, 4 banks, 24 bars, etc.), is the second important economic ambit, as its source of invigoration are the results of the fishing activities, that is to say, it is particularly sensitive to all the fluctuations which affect the latter. The success or failure of the catches affect the social relations and the economics of the community. If the fishermen do not catch anything, the fishermen's wives are obliged to dip into their savings in order to lend a hand, or to obtain food and sundry items on credit, until such time as the catch is more successful.

## 3. THE STRUCTURE OF THE FLEET

At present the fleet is made up of 73 vessels, varying in size and the type of work carried out. They can be classified into three large groups : The "gamelas" group, 40 vessels with a "eslora" of not more than 6 metres, powered by outboard motors. Each "gamela" is crewed by one or two men and its principal activity is the catching of crustaceans and molluscs ; in winter in the interior of the "ría" and in summer off the coast. In the "motoras" group there are 12 vessels. They have between 5 and 12 T.R.B., powered by motors of up to 200 H.P., a crew of up to 6 and their fishing techniques and types of catch are much more varied. They use different methods such as, trammel net, fish trap, seine-net,..., aimed at catching various species (octopus, hake, conger, spider craf,...). Their principal fishing grounds are between the coast and seven miles out. Finally we have the "palangreros" group, with a total of 21 vessels. They are the largest boats of all with between 15 and 100 T.R.B., and crews of up to 11. For practically the whole year, they fish in the area known as "El Cantil" (between 14 and 30 nautical miles from the coast) using the long-line ("palangre") technique. Our interest will be centered on this third group.

The boats equiped with long-lines are more specialized but less versatile vessels. During times of poor catches, some fishermen complement the long-line with the "rasco" (a varieted of gill net) and at certains times of the year (January to March) gill-nets are used. However the boats equiped with long-lines, have since 1968, concentrated their fishing activities in the fishing ground known as "El Cantil de Muxía". A fishing ground situated between 15-30 miles from the base port and with an extension of approximatly 16 square miles. It is a relatively homogenous area, whose limits come to be defined by their productivity, in which the resources are dense and predictable. This maritime area is lined along the continental platform, a very rugged area, consisting of major elevations and submarine valleys, which together with strong currents and outcrops of nutrients make it especially productive. Graphically it resembles a narrow strip of between 2 to 3 miles wide, which is prolonged uninterruptedly for 14 miles. It is here that the four principal fishing grounds which follow are distributed, "Quiniela", "Crimen", "Petón das Navidades", and "Papeles".

The wealth of these fishing grounds lured the attention of the fishing community of Muxía at a time (1964) when the coastal fisheries were showing evidence of a certain depletion. The absence of alternative fishing grounds at close proximity, combined with the difficulty involved in specializing in other types of more profitable fishing, forced the fishing community to concentrate on "El Cantil" as a way of improving their economic expectations.

However the entry into this territory brought with it a need to reform the structural conditions of the fleet, they had to be adapted to the characteristics which the new area presented. Due to this, the history of the long-line boats of Muxía is the result of a process of "conquest" in that in order to make their way to "El Cantil" and assure their permanence there, it was necessary to modify the former production system, and to compete with vessels from other communities. The problems that were posed in the entire process were brought about by a series of factors : the size of the fishing area, technology, the composition and the distribution of the species, the physical aspects of the environment, the alternative employment opportunity, legal loopholes,.... which all led to the creation of a territorial system practising an exploitation régime of common property use. It also led to the setting up of a co-operative negotiating model of the resources and benefits.

## 4. TECHNOLOGY AS A LIMITING FACTOR IN THE ACCESS TO THE CANTIL

From the outset of the twentieth century until the 1940's, the community lived in a situation of tight dependence on the rural environment. Fishing was the only source of gain, but insufficient to cover the basic necessities, which in turn had to be met by the agricultural products of the neighbouring villages. Due to geografical isolation, the limited value of the sea produce and the difficulty in commercializing it, the community was unable to reach a similar level of development that other Galician ports were benefiting from. During this period the community did not undergo significant changes. Onshore fishing was carried out (maximum 7 miles from the coast), using traditional fishing instruments and materials, and vessels unable to respond in the most effective way to envoirnmental changes.

The years that followed the Civil War, until the mid-sixties, are characterized by a period of transition, of a pre-capitalist method of production toward a process of modernization. Certain traditional methods of orientation, localization of fishing boats, and sea bed surveying were gradually done away with. Another part of this remodeling included the

abandoning of hand sounding, while at the same time new materials with added resistance, such as nylon were introduced in place of hemp and cotton. New styles of fishing were also introduced, while new apparatus for the surveying of the sea bed and the detection of shoals of fish meant a significant rise in production.

The appearence of more modern types of sounding in 1962, allowed a more meticulous exploration of the fishing grounds and also permitted an extension of the actual working area. This also contributed to important decision taking as far as entering into the rich fishing grounds outside of the usual limits was concerned. In our opinion, the introduction of modern methods of sounding in some of the production units was the determining factor in the decison to establish contact in the fishing grounds of " El Cantil "

There is evidence that in 1964 vessels form A Guarda (Pontevedra) and Finisterre( La Coruña) had already spent two and four years respectively, fishing in "El Cantil" grounds, with exceptional catch results. However the still deficient equipment of the productions units of Muxia represented for them a restrictive factor. They were not competitive enough to break through certain envoirnmental restrictions, such as bad weather, visibility, distance to the fishing grounds, etc.. As the new methods of sounding were able to orientate them in the surveying of the sea bed of "El Cantil" the overall effect of these restrictions was somewhat diminished. In fact in the summer of 1965, taking advantage of the good weather and visibility conditions, two vessels were able to break the 7-mile barrier, penetrating into this area, identified by its depth (300-400 fathoms) and the marked sinuosity of its underwater relief.

However access and regular permanence in "El Cantil" was still a long way off for the fishermen of Muxía. The unfavourable weather conditions (winds, fog, currents), the situation on a maritime traffic route, the presence of French boats fishing in the area, certain fluctuations in the resources, underdeveloped fishing techniques, etc, were the problems that the fishermen were faced with, some were problems of a physical nature and others were those induced by the effects of a socioeconomics setting in expansion, to which there was no immediate answer. Until 1968 the incursions into the new found area were only occasional and of a seasonal nature, alternating onshore winter fishing with summer fishing in "El Cantil".

The response to the overcoming of these limiting factors underwent a period of capitilization which made the acquisition of technology and improved vessel possible. The fishing ground wealth represented a guarantee which covered the risks of the heavy investments that were needed to orientate an onshore traditional type of fishing toward a more sophisticated type of fishing. In addition to this the decision making was tied up with expectations derived from future fishing. The capital which was invested was obtained principally from family savings, bank loans, and the easy-payment facilities which were offered by shops specialized in electronic aparatus and some boat builders.

It was not until the beginning of 1970 that the process of innovation became obvious, with the acquisition of more powerful boat engines and the incorporation of great depth. water sounding. From here on the growth of the fleet was set apart by newly built boats, a rapid increase in GRT and HP and by the adoption of more advanced technology (VHF, Gonio, winding engines).

The most significant innovation was the incorporation of the radar (1972) and the Decca system of navigation. These systems brought with it three major advances, it allowed safer navigation during bad visibility conditions. It allowed the situation of the boat to be known at all times, and last but not least it allowed the exact indication of the most productive fishing areas. This was probably the most advantageous and decisive tool which can be used as a response in order to justify, to a certain extent, a continual presence in the "El Cantil" fishing grounds since 1972.

The history of the technological development of the Muxía fleet is the response to a series of limitations which restricted the continual access to a fishing ground containing dense and relatively predictable resources. These were adaptable responses in that they met the needs of the fishermen advantageously at all times. The technology seems like a strategy which reveals the limitations and constrictions that affect the production processes. With innovation as a response, the units become more competitive not only in overcoming envoirnmental chance but also in order to be able to compete in better conditions than those of A Guarda and Fimisterre. It also represented an accelerated change with respect to the methods of production of the old system, coinciding with a period of industrial development in the state framework, where social and economic demands made traditional systems obsolete and unadaptable. The absence of new technology in this sense acts as a restricting function in the adaptation of the economic rationale. Its acquisition permits the possibility of greater control over the variations and fluctuations of the resources, entering into and fixing a stable method in an area which was previously prohibited and at the same time boasting the capacity of the production and becoming more competitive with respect to other producers.

## 5. "EL CANTIL" : THE RESOURCES, FISHING, AND THE VESSELS

"El Cantil" signifies for the fishermen of the village :

"a maior riquesa que podemos ter aquí en muitos anos,..., fui unha verdadeira mina de ouro " (The greatest source of wealth that we have had here in many years, a real goldmine").

From the early years until the beginning of the eighties a boat could fish in only one day more than 1.000 kilos of hake (in 1979 14,44 % of the hake unloaded in Galicia (17.325 metric tonnes.) was landed in Muxía : Varela de la Fuente, Manuel : 1985 :213.)). It also represented an area highly concentrated with a variety of resources. More than twenty species of commercial interest can be catalogued, although the fishing endeavour in the first years of its exploitation, concentrated mainly on the capture of hake (Merluccius merluccius), sea bream (Pagellus cenetrodontus), grouper (Serranus guaza), palometa (Brama raii) and red palometa (Beryx decadactylus). Hake and sea bream, species which give a high return, were always subject to the greatest control, in as far as one could predict with ease the seasonal variations in each.

All species are fished with long-lines, in two different ways : the deep sea method ; aimed at bethonic species, and with surface palangre, for the pelagic varieties. The differences between the two are in the amount of lead necessary to sink them to the desired depth.

The equipment involved requires substantial space to be thrown, as they can measure, in this case, up to to 6 km in length and contain 5000 hooks. They are easy to handle and can be stored in great numbers. Their construction and maintenance are simple and low in cost, given that only the line and hook are involved. This was an important factor when choosing this method in preference to that of the gill net (widely used in the 50s and 60s).

As this is an area with clearly defined "boundaries" (the sinuosity of the seabed being correlated with surface coordinates), it is simple for the fishermen to know where the fish are concentrated, "altos e caídas das montañas" (peaks and slopes of the mountains). Howeverm the physical characteristics of the area (size and shape) will determine the number of boats which can work there simultaneously.

Indeed, the fishermen themselves were aware of this fact, and taking into account the different methods involved, calculated that the fishing grounds could not deal with more than 18 or 20 units.

In 1960, the Cantil began to be worked by six boats from A Guarda. In 1962, 10 more arrived from Finisterre and from 1968 onwards, boats from Muxía gradually increased their presence, starting with 10 and reaching 27 by 1972. This high density of production units within a structurally limited area, which used, moreover, fishing equipment such as the palangres which require a lot of space, was the principal cause of the conflict which arose between the various parties involved.

To these variables were added others, of various kinds, which had an influence on the increase in tensions. The underwater currents (an ecological factor), gave rise to long-lines becoming tangled with others and thus affecting the relationship (social) between the fishermen, given that they had to decide who the fish in the tangled equipment belonged to (legal vacuum). This question was usually resolved by dividing the total catch into equal parts for all those involved ("ir a compañía"). However, deception and underhand tactics led to the frequent obstruction of this practice (nistrust as a psychological factor). The first one to raise his long-lines kept the whole catch ("roubaban" - they stole), which gave rise to conflict and menaces between the various producers. Nevertheless, this sort of incident tended to occur between producers of different communities. When the parties involved were from the same town, the former practice was normally respected (social cohesion factor).

## 6. ESTABLISHING THE PROBLEM ; EVENTUAL SOLUTION

The problems that the fishermen of Muxía had to overcome were not only related to the acquisition of the technology necessary to get to the fishing grounds. They also had to appropriate the Cantil to ensure their continued presence there and to consolidate a stable exploitation. The latter question is the central idea of this paper.

In such a competitive and conflictive situation, initially caused by the concentration of boats in a relatively small area, friction between the various producers was inevitable. It was a situation which caused a decrease in production to such

an extent that the survival of certain social groups was put at risk. New technology, despite providing better oportunities for the fishermen of Muxía, did not solve the main problem : to ensure the viability of potentially rich fishing grounds, when the latter was threatened by the presence of fishermen from other communities. All of the elementary rules which normally guide the fishing community were broken. Neither where the long-lines had been cast nor their order of casting was respected, generating a situation of anomie as far as production was concerned. With things in this state, Hardin appears to be correct when he states that fishermen behave like "anarchic villains". Not only do producers deplete the resources, they also hinder the activities of others. At this time, the Solomon-like formula of "ir a compañía" only worked between producers of the same town, thus reinforcing the links of identity between fishermen of the same community. This was the starting point for the fishermen of Muxía, who had the greatest number of boats, to begin to use force as a weapon of persuasion. Violence, as a real or ritualised phenomenon (simulations of boarding or chasing other vessels etc..) acted as a way to impose and maintain control over the area. Due to this type of action and the fact that the other communities were farther from the zone, fishermen from other towns (firstly those from A Garda in 1971 and boats from Finisterre a year later) began to abandon the Cantil.

Through a strategy of perimetric defence, where the boundaries of the territory were marked by the presence of boats from Muxía, boats from other communities were dissuaded from approaching the area. This social barrier towards fishermen of other communities had a function which was both dissuasory and distancing.

From this moment on, the systen of open access was converted into one of exploitation of common property (according to the distinction made by Berker and Farvar, 1989). This implied denying the same right to the fishermen of A Garda and Finisterre, as the group from Muxía, being all from the same community, retained exclusive access to the resources.

But the fundamental problem remained ; the high concentration of boats in a limited area. The Cantil fishing grounds can handle 18-20 production units ; in 1972, there were already 27. During this year and the following one, the level of internal competitiveness reached dangerous levels as far as social stability was concerned. The growth process reproduced the competitive scenarios of earlier times, except that now the economic and social differences between the various producers were emphasised. The most powerful boat reached the fishing grounds first and thus got to choose the best spot. The only team spirit involved now seemed to be the rivalry between the fastest boats. The result of all this was that the producers with the fastest boats got richer while the others got poorer, "porque si tí larjas en este mar e matas 10 caixas e eu unha... pois non podía ser. Entonses dábase, que o que tiña millores máquinas chejaba antes e tiña preferensia. E os outros a larjar por terra ou por fora. E entonses chejou a un serto extremo que xa non se dormía na cama" (Because if you fish here and bring in 10 boxes and I only bring in one... well, that's just not on. Anyway, what happened was that whoever had the best boats arrived first and had preference. And everyone else had to cast near land or further out to sea. And we ended up hardly ever going to bed.) The different boats found themselves in a constant race to see who could get to the fishing grounds first ; a vicious circle which only hurt the fishermen themselves. "... sobre as 7 da tarde cando chejábamos do mar, cambiámonos de calsetins e a bordo outra ves para salir ao mar e coller sitio... xa dormíamos no mar, e ao millor para non janar patacón por que viña aquel e ¡pelábache !" (At about 7 in the evening when we arrived home, we'd change our socks and go out to sea again to get and save a place... we were even sleeping at sea, because maybe then we'd wouldn't end up with nothing, 'cause the other guy'd come and take your catch off you). The incidents not only took place on a professional level but also between neighbours or relatives. In this way, tension at work (productive ones) were translated into social unease on land which had its effect on the community. Any conflict was emphasised by the problems which existed at sea. Therefore, not only social norms but also a sense of values was put at risk.

Faced with the need to restore not only social tradition but also that of production, the shipowners decided the create the basis for a system of equal production which would avoid conflict and make production profitable again without risking the livelihood of any of the parties involved.

In November 1973, A Compañía emerged as a way to "institutionalize" and manage efficiently the resources of and access to the Cantil. An informal set-up which, given the legal vacuum, enabled them to legitimize their exclusive rights of access to these communal-property resources where the exclusion of outsiders (the rest of the local communities) was achieved through use of a perimeter of cooperative defence. The acceptance of this right of communal-property on the part of the other fishing villages was clearly demonstrated in 1980 when certain boats from the nearby town of Camariñas wanted to fish in the waters of El Cantil. They based their claim on a rule which works in most Galician fishing communities (fundamentally for fishing grounds which are geographically stable) which states that the right to operate in a certain area depends upon the distance between it and the home port of the boats. The nearer your town was, the more rights you had.

The fact that the two towns were equidistant from the Cantil led to the community of Muxía (who had succeeded in appropriating the Cantil at a high cost) conceding in part the claim of the fishermen from Camariñas (traditional rivals). However, the concession was accompanied by the proviso that the others should use the long-line method exclusively and only after two o'clock in the afternoon.. "deixámoslos vir por non armar outro batifondo pero sempre baixo as nosas condisions, podían pescar pero despois de nos. Eles podían larjar po-la tarde ¡sempre e cando nos terminasemos ! e a sabendas que o millor lanse a larja é o de alborada" (We let them come to avoid any more quarrels, but on our terms. The could fish there, but only after us. They could cast their long-lines in the afternoon, providing that we'd finished ! and they knew that the best catch was to be made in the morning). This condition considerably limited the productive capacity of the boats from Camariñas. With winter coming on, the daylight hours were decreasing and long-lining was made increasingly difficult. This led to only a sporadic presence by the others and eventuall they give up coming altogether.

## 7. ORGANIZATIONAL BASIS OF A COMPAÑÍA : DESIGN

The name "A Compañía" has its origins in a traditional way of resolving ownership problems over resources brought in under certain conditions.

Both because of the way they distributed the production units in the fishing grounds and the method of organizing the extraction process and division of catch on an equal basis, this could be described as a cooperative system of production.

Within the Cantil, various sub-divisions of territory existed : Quiniela, Crimen, Navidades, and Papeles. The fishermen were aware of the approximate productivity levels of each of these due to their average daily catch. Consequently one of the shipowners (one of the most competent) organized once a week, on a drawing-lots basis, which area corresponded to which boat. In this way, they could fish in the most efficient manner and also lay their long-lines at the appropriate distances to avoid their getting tangled. Each crew knew in advance which area corresponded to their boat.

The second point controlled the amount of equipment permitted on each boat. All of then had to lay an equal number of long-lines, a number which increased progressively over the years.

The third point obliged all the crews to land their catch in their home port.

And finally, the income of the sale had to be distributed equally between all the shipowners so that he, in turn, could divide the profits according to the "a parte" system among the crew (half for the boat, half for the crew).

Nevertheless, there existed other inequalities which could act as destabilizing factors. The differences between the boats was reflected in their overheads (fuel costs, social security etc...) and if in some boats there was a larger crew, profits were made smaller both for the crew member and the owner. But these disadvantages were ostensibly overlooked, communal rights taking priority. Other costs were met "a Monte Mayor", that's to say from the total turnover of the whole fleet in that day.

The company came into being right from the start as the only way to peacefully exploit these limited resources that were subject to the law of diminishing returns. But it was not purely a method to make production more profitable ; it also served to alleviate tension within the community and between neighbouring towns. Moreover, it was a social solution arising from the whole community (family, neighbours etc...) and aimed at reestablishing the traditional social order. From this point of view, the appropriation of the fishing grounds by the producers of the same community demonstrates how social relationships can be the framework for those of production (productive relationships).

However, A Compañía's way of organizing production led to negative consequences which threatened its existence on at least two occasions (1974 and 1975) ; and for similar reasons on both occasions. The equal division of profits cuased some producers to become apathetic. In this sense irregularities arose in the work process. Some vessels used less long-lines than they were supposed to. Others did not put all the bait necessary on their hooks. Moreover, some producers used less efficient equipment and materials ; cheaper hooks and line. Some even skimped on the amount of lead they used to sink the long-lines. A group of supervisors (enjoying considerable social prestige) was formed to check on this sort of irregular activity. Economic defence, not so much of the area, but more of the way in which the production was organized, was therefore determined by the interaction and assumption of rules inherent in the extra-active activity itself.

Despite these irregularities, the criteria of A Compañía were consistently adhered to as long as the resources were abundant and predictable.

When the resources, because of their seasonal variability, decrease in quantity and become less predictable, above all the most profitable species (hake and sea bream), the exploitation method laid down by A Compañía is temporarily set aside.

The defendibiblity of the territory in these circumstances is not essential. Consequently the units involved change their territorial behaviour to a "non-territorial" one as a direct result of the seasonal alteration in the distribution of the resources. What happens is that the fishermen tend to disband and move into other fishing grounds (in El Cantil and further out to sea), increasing their working area and thus their possibilities of find a zone richer in resources. Each producer has a free choice of where he will cast his long-lines. Here, personal knowledge and experience appears as a function in the making of individual decisions. When a substantial find is made, A Compañía reorganizes its production process accordingly.

## 8. CONCLUSION

We have attempted to demonstrate that in a deficient economic environment where employment prospects are restricted, the appearance of a stable area, rich in resources, presents the members of a fishing community (during a time of low productivity of its traditional catches) with the conditions for its social reproduction.

We have seen also how the presence of "external" competitors, who endangered their stabilty, led them to protect their fishing grounds through the use of force, and how the appropriation does not become effective until a formula for the equal division of profits among the members of the community is discovered.

In this whole process, we have wished to underline how the rights to common-property resources, when the latter are abundant, predictable and in a stable area, are altered in favour of that competing group who have been able to create the conditions necessary for their appropriation.

ABSTRACT

*In the management of many of the world's important fish resources, fisheries economic models are applied to help the authorities to find the most appropriate management method. Some of the management schemes are based on the allocation of an individual, annual fishing quota to every vessel participating in the fishery.*

*In these models of the optimal harvesting of a fishing fleet from a given fish stock, it has usually been assumed that the unit sales price of the fish caught is a given constant. Some studies have addressed the demand/supply characteristics, while other sources of price variability have not been dealt with.*

*In this paper, we focus on the impact of product mix decisions, made by the operators in the fisheries, on the sales prices and on the optimal, individual fishing quota allocated to each vessel. It is shown that an optimal fisheries management scheme should not be determined without considering the market prices and the production attributes of the fish products. Also, contrary to the fisheries economic models to now, it is not necessarily optimal to give as high quota as possible to each vessel, and thus to operate as few vessel as possible.*

## 1. INTRODUCTION

Since the middle of the seventies, most of coastal states of the world have extended their fisheries jurisdiction and nationalized their fishing grounds. Concern about the danger of over exploiting the fish resources has increased, so that now, few fisheries are expanding, and many are in fact in phase of declining.

Most of the fisheries nations have in the last years and decades been implementing, or at least discussing various methods (schemes) to regulate the fisheries. Although the objective may not always seem clear, in most cases it is a composition of stock conservation, economic resource utilization and social/regional political goals.

A convenient classification of these management schemes is given in Lawson 1984. One of the categories is the method of catch quotas, which can be divided into two main classes :

The "Olympic" System : A single overall quota, i.e. Total Allowable Catch (TAC) for the fishery, such that access is open to the fishery until TAC is reached.

The Individual Quota (IQ) System : The TAC is divided and allocated as annual catch quotas to the n vessels (or factories or groups).

In theory, if the fleet is homogenous, this means that IQ * n = TAC. The case of open access can be regarded as the special case of infinite TAC, and infinite IQs. Also, the IQs may be transferrable, in which case they are called ITQs.

The determination of TAC, i.e. how much to harvest from a fish stock annually, is often based on bio - economic models, which are the products of fisheries economics, a 20 - 30 years old discipline. These models have been used successfully to gain a deeper understanding of the dynamics of fisheries. For real life policy making and decision support, they have been criticized for being too simplistic (Helgason and Òlafsson 1988).

In these models, see for example Hannesson 1974, it has usually been assumed that the sales price of the fish, or rather of the fish products, is fixed. This implies that the revenue increases linearly with the allocated quota, up to the annual catch limit for the vessel, which in turn implies a "bang - bang" type of an economically optimal quota allocation : Either maximal annual quota, $IQ_{max}$, to a vessel, or zero. This is in accordance with the fact that no one seems to have questioned that, for a certain fishery with a given TAC, the number of vessels n should be as low as possible, if an economically optimal solution is to be reached.

In this paper, we will study the impact of product mix on these fundamental assumptions, and on the very important question of an optimal allocation of quotas. In section 2, we start with a harvesting model, which is as simple as possible to keep the presentation of our ideas clear. We define product mix in section 3 and add it to the model, which is then solved in section 4.Section 5 deals with the question of fleet size. In section 6, we present the results of simulation experiments to support our findings. In conclusion, the impact of our results is summarized.

## 2. A SIMPLE HARVESTING MODEL

We consider the annual, sustainable harvesting from a fish stock by a homogenous fleet, and introduce the following notation, in addition to the previously defined symbols :

n : Number of vessels

E : Total annual effort, for all vessels, for example time at sea catching

Y : Yield, or annual harvest, a function of E, Y(E)

P : Price of fish paid by the market

CE : Cost associated with each unit of effort (variable operating costs)

CV : Cost associated with each vessel (annual fixed operating costs)

e : Upper limit on annual effort per vessel, i.e. max time at sea per year for eachvessel given the annual catch $IQ_{max}$.

We assume the following, for clarity reasons :

- The fishermen are price takers, i.e. the quantity of fish products placed on the market by this fishery is too small to have any significant effect on the price
- A single species stock is considered
- The fleet is homogenous, i.e. all vessels are alike

- The cost of fishing is a linear function of E (variable operating costs per vessel) and n (annual fixed costs per vessel)

Then, the optimal effort is found by solving model (1) :

$$\text{Max } Z = P * Y(E) - CV * n - CE * E \quad (1.1)$$

$$e * n \geq E \quad (1.2)$$

$$IQ * n = Y(E) \quad (1.3)$$

$$E, n, IQ \geq 0 \quad (1.4)$$

Let us also define the average Catch Rate, CR (average yield per unit of effort) as

$$CR(E) = Y(E)/E$$

When solving this model, it becomes clear that n should always be as small as possible, and the individual quota IQ accordingly as large as possible, that is

$$n = E/e \text{ in } (1.2), \text{ and } IQ = IQ_{max}(E) = e * CR(E)$$

Keeping this triviality in mind, we get a well known solution to (1) :

$$P * Y'(E) = (CE + CV/e) \Rightarrow E1 \text{ and } Z1 \text{ (and } n1 \text{ and } IQ1)$$

see fig. 1, where the bioeconomic equilibrium at point *a* is also shown.

Let us assume as a hypothetical scenario that we have an open access fishery in state of equilibrium with $n_{eq} = E_{eq}/e$ vessels participating. A natural conclusion from model (1) would be to reduce the number of vessels to $n1 = E1/e$, with each vessel fishing $IQ1 = IQ_{max} = CR(E1)*e$ per year.

In fact, this scenario is by many experts believed to true for many fisheries of the world, and the conclusion drawn above is a commonly heard advice from fisheries economists and other experts. To take Iceland as an example, experts have stated that the fleet should be reduced by 30 - 40 %, see for example a collection of articles by number of experts, edited by Helgason and Jónsson 1990.

## 3. INTRODUCING THE PRODUCT MIX

Fish processing is a divergent production process, frequently resulting in a great number of alternative products from the same raw material. To take an example, a production manager may at any given time have the possibility to produce any of tens of different products from a load of cod.

These alternative products differ in prices and capacity requirements. Typically, there is a broad range between the most valuable product, which usually is the most labor intensive product, to the lowest priced but "fastest" product (Arnarson, Johnston 1990 and Johnston et al. 1990).

This is easier to understand by considering the processing stages in fish processing. To take the production of fillets as an example, the main stages are gutting, heading, filleting, skinning, trimming, packing and freezing. Many combinations of skipping some of these stages exist, leading to a variety of products. And by skipping processing stages like trimming, the production rate is greatly increased, usually at the cost of much lower price, depending on market segments preferences.

The product mix is well known and appreciated in fish processing, as the managers make use of it to absorb day to day randomness, at least to some degree. Fish is a highly perishable raw material, and at times of lively fishing, it is important to be able to speed up the processing by choosing "fast" products to save the raw material from spoiling.

Also, the product mix possibilities are used to adjust, in a more long term sense than day to day, the production process to a given capacity, and thus to balance the processing by variating the fishing operation. This applies in principle whether the processing is on shore or at sea. However, the impact of product mix can be seen more clearly in the case of processing at sea. Furthermore the factory trawler can be treadet as two companies or units where one operation is responsible for the production and the other for the fishing operation. That fact makes it easier apply the methods for mixed operation of shore based plants and factory trawlers later if it is feasible. Therefore, we will in the following restrict ourselves to discuss factory trawlers only.

In Jensson 1988, the product mix problem in fish processing is formulated as a linear programming problem, maximizing revenue with available raw material as one of the right hand sides (RHS). From the theory of linear programming, it is known that the revenue increases with a RHS in a concave, piece wise linear manner.

The operation of a factory trawler over a year can be regarded in a similar way (however more complicated, see Arnarson and Jensson 1991), with the allocated, individual quota as one of the RHS. In our case, it is therefore not unnatural to assume the general form in fig. 2 for the revenue R of a single vessel as a function of quota IQ.

Now, we have dropped the assumption of a single sales price P, and introduced a range of products and prices, such that

> $\mathbf{P_m}$ : Price for most valuable, and labor intensive, product. This would be the only product produced in case of a very small annual quota.
>
> $\mathbf{P_l}$ : Price for least valuable, but "fastest" product. This would be the only product produced in case of maximal possible quota $IQ_{max}$.

The revenue function R(IQ) increases first marginally by $P_m$ , but eventually the marginal increase becomes zero, when the vessel cannot catch the allocated quota anymore.

From fig 2, we can now deduct a general form for the average price AP and the marginal price MP at each quota level IQ, see figure 3.

Instead of our previous harvesting model (1), we now have model (2) :

$$\max Z = AP(IQ) * Y(E) - CV * n - CE * E \tag{2.1}$$

$$e * n \geq E \tag{2.2}$$

$$IQ * n = Y(E) \tag{2.3}$$

$$E, n, IQ \geq 0 \tag{2.4}$$

The only difference between (1) and (2) is that the price is no longer fixed, which is sufficient to cause the fact that n and IQ no longer have trivial solutions, as will be seen in the next section.

## 4. THE EXISTENCE OF AN OPTIMAL QUOTA

To solve model (2), we first eliminate n using (2.3), which gives

$$\max z = [\ AP(IQ) - CV/IQ\ ] * Y(E) - CE * EE,\ IQ \geq 0,\ IQ \Leftarrow IQ_{max}(E) = e*CR(E)$$

Let us either relax the upper limit on IQ or, which is more realistic, assume that IQmax is independent of E. Then we see that the model can be solved in two steps :

*Step 1 :* Determine $IQ = IQ_{opt}$ by maximizing the "net price"

$$\max NP(IQ) = [\ AP(IQ) - CV/IQ\ ]$$
$$0 \leq IQ \leq IQ_{max}$$

It is important to note that determining the optimal quota $IQ_{opt}$ is independent of determining the effort E and the harvest Y(E). Figure 4 shows how $IQ_{opt}$ is found.

The solution is derived from

$$IQ_{opt} = SQRT( CV/(-AP'(IQ_{opt} )) \Rightarrow IQ_{opt}$$

*Step 2 :* Determine the optimal effort E on basis of $IQ_{opt}$ and $NP(IQ_{opt})$

$$\max z = NP(IQ_{opt}) * Y(E) - CE * E$$
$$E \geq 0$$

resulting in the solution

$$NP(IQ_{opt}) * Y'(E) = CE \Rightarrow E_{opt}$$

To conclude this section, we notice that the question of how much quota should be allocated to each vessel can be separated from the determination of the rate of harvesting the fish stock, or in other words the determination of Total Allowable Catch TAC. Determining the size of the individual quota for each factory trawler is only dependent on the products (the market prices and the production attributes of the products) and the annual cost of operation the trawler CV.

## 5. THE FLEET SIZE

It can be shown that, under reasonable assumptions, when comparing the solutions to model (1) and model (2), the following is true :

$$n_{opt} > n1,\ IQ_{opt} < IQ1 = IQ_{max},\ E_{opt} > E1 \text{ and } Z_{opt} > Z1$$

So, taking the product mix into account, more vessels should be operated than concluded earlier from model (1), with less than maximal quota each, resulting in a higher rate of harvesting and returns.

Turning back to the scenario discussed at the end of section 2, it should now be clear that reducing the fleet to n1 is not an optimal solution. It may even not be any better than keeping the present number of vessels $N_{eq}$ unchanged, but imposing individual quotas of appropriate size.

Let us briefly study the impact of product mix on the fleet size, under the simplifying assumption that the effort E, and the total yield Y, is predetermined, i.e. a TAC = Y(E) is given.

By inserting IQ = TAC/n into model (2), we get model (3)

$$\max Z(n) = P(TAC/n) * TAC - CV * n \quad (3.1)$$

$$n \geq 0 \quad (3.2)$$

Figure. 5 shows the nature of the total revenue function for the fleet Z(n), and the cost function CV*n.

For a small fleet, not capable of fishing the TAC, the revenue first increases linearly by $P_1*IQ_{max}$, as all vessels have maximal quota and all the catches go to production of the "fastest" product, giving the sales price $P_1$. Increasing n to more than necessary to catch the TAC will give the vessels more time to produce more valuable products.

From fig. 5 we see how the error made by operating n1 vessels, compared to $n_{opt}$, depends on the difference between $P_m$ and $P_1$, as well as on the vessel cost CV.

## 6. RESULTS OF SIMULATIONS

The purpose with the models presented above was to demonstrate the impact of product mix on fisheries management in a simple and clear manner. They are of course much too simplistic to apply directly to any real life fishery.

To support the findings in this paper, a detailed simulation model of the operation of a factory trawler was built. The model and it's assumptions are presented in Arnarson and Jensson 1991. The model can be adjusted to practically any kind of factory trawlers and fisheries. In the following, we will see the results of model runs for the Icelandic factory trawlers fishing cod.

To summarize briefly the main assumptions for the simulation, the vessels are characterized by the following stereotype factory trawler :

| | |
|---|---|
| Fish Hold Capacity | 250 metric tons |
| Crew Size | 24 men (8 per shift in processing) |
| Max Trip Duration | 24 days (plus 3 for steaming and landing) |
| Fileting Capacity | 34 fish/minute |
| Freezing Capacity | 49 kg/minute |
| Catch Rate Distribution | LogNormal kg/hour |
| Mean Values (low - high) | 799 kg/h in dec. - 1385 kg/h in aug. |
| Trawling Time/Haul | 1 - 6 hours |

The products that can be produced by the trawler in these simulation experiments are :

| Product | Price (IKR/kg) | Labor req. (min/kg) | Raw mat. req. (kg fish/kg) |
|---|---|---|---|
| AM fillets (skinless, boneless) | 350 | 2.79 | 2.67 |
| RL fillets (skinless, with bones) | 213 | 2.56 | 2.26 |
| OSN fillets (with skin and bones) | 149 | 0.41 | 1.96 |
| HEI (H whole frozen fish) | 69 | 0.13 | 1 |

Also, mince blocks are produced as byproducts of the fillet products. Other assumptions can be found in Arnarson and Jensson 1991.

The model trawler was operated with different quota allocated. As would be expected, and as can be observed in reality, more of the "faster" products are produced as the quota increases, see figure 6.

The results shown in figure 6 witness that the decision behavior of the captain is realistic, which is of great importance for the interpretation of the simulated results.

Figure 7 shows how the revenue of the trawler increases with quota. This should be compared with the hypothesis in figure 2.

In the same way figure 8 shows the simulation results comparable with the postulated average and marginal price functions of quota in figure 3. And figure 9, where it is assumed that TAC is 300,000 metric tons of cod, and $IQ_{max}$ is 5,000 metric tons, is comparable to figure 5.

## 7. CONCLUSION

In this paper, we restricted our discussion to factory trawlers, where product mix decisions are made for the catch of each haul. In principle, our findings should apply as well to shore based processing buying the fish from fishing vessels. The main difference is that the product mix decisions are made for each trip, or each day. Also, the price differentiation between the products should then be reflected in the fish prices offered by the processing plants, which depends on factors as ownership, operations traditions and fish markets.

The product mix is one of the more important characteristics of fish processing management. Until now, it's impact has been overlooked in the literature of fisheries economics and management, although product mix is certainly not ignored by decision makers in the firms in their daily practice.

The main impact of product mix on quota allocation in fisheries management was shown to be the existence of an optimal individual catch quota, which is less than the maximally possible quota for each vessel. A consequence of this is that a fishing fleet should not necessarily consist of as few vessels as possible, as seems to have been believed, or at least implicitly assumed.

Although it is outside the scope of this paper, it should be mentioned here that other significant arguments point in the same direction regarding the fleet size of many fishing nations of theworld, opposing the commonly heard advice to reduce greatly the number of vessels. To list some :

(i) The sales value of existing fishing vessels on the world market is low (i.e. the cost coefficient CV, including the opportunity cost of a vessel, is low, which results in lower quotas and more vessels in the analysis in this paper).

(ii) Regional political problems, which are very common in fishing areas, usually become more difficult to solve when cutting down the fleet.

(iii) Year to year fluctuations in catches and markets, and the possibility of new fishing opportunities argue for a certain slack or even over capacity.

(iv) Fish finding often is more difficult when the vessels are fewer.

These arguments, and the product mix impact, have to be considered carefully before it is concluded that a "most economical" solution should be advocated and a fishing fleet should be reduced. However it may proven to be difficult in real fishery to realistically set optimal quota. As discussed above the optimal quota is depended on the product mix and therefore the market prices for the products. The factors influencing market prices are many and complex, such as currency rates (See Johnston et al 1990), and on the input factors complex ecosystems contribute to do the task lesser feasible. This is specially true in the fishery of North-, Atlantic and Pacific where the fishery is industrialised and competing on the world markets.

The simulation results in the last section support the hypothesis made in section 3 regarding the impact of product mix. For further evidence, an empirical study should be the next step. One of it's goal would be to analyse in depth the decision behaviour of the captains and the operators.

# Distribution and Processing by P. Guillotreau

Bien que dérivés de l'exploitation de ressources naturelles renouvelables, dont la spécificité requiert une réflexion économique originale, les secteurs de la transformation et de la distribution des produits de la mer s'apparentent davantage aux activités industrielles plus « classiques » par leur structure et leur mode de fonctionnement. A ce titre, leur analyse peut se concevoir à la lumière d'outils économiques développés notamment par le champ de *l'économie industrielle*. Ces outils s'inscrivent dans trois principaux courants théoriques. Le premier est issu de l'approche classique, avec le triptyque « Structures de marché-comportements-performances » initié par J. Bain en 1959, à la suite des travaux de Robinson et Chamberlain. Son application à l'industrie des pêches prise en tant que filière génère des problématiques relatives à la concurrence des marchés des produits de la mer, au changement technique et à ses effets, au comportement stratégique des acteurs et à la nature des relations clients-fournisseurs à tous les stades de la filière ou encore à la rentabilité des différents segments qui composent la filière. Le second courant théorique, issu de l'approche néo-classique, s'est développé autour de la théorie de la concurrence imparfaite et de la théorie des jeux. Son application aux industries connexes de la pêche permet d'aborder les questions relatives aux caractéristiques des produits (qualité, différenciation, compatibilité...), des entreprises (existence de réseaux, de coopération) et des marchés, afin de définir des modèles d'interactions entre entreprises du secteur. Enfin, le dernier courant théorique est issu de la théorie des organisations autour des travaux de Coase et Alchian et aborde les conditions d'organisation et de croissance des entreprises, la nature du capital et des comportements des partenaires de l'entreprise.

Outre cette dimension industrielle, la nette accélération des phénomènes concourant à la globalisation de la filière pêche lors de la décennie écoulée, milite en faveur d'une intégration plus systématique des théories de

Although deriving from the exploitation of renewable natural resources whose character requires a specific economic theory, sectors concerned with the processing and distribution of sea products are more closely connected to more "classic" industrial activities in their structure and their modes of operation. Therefore, they can be studied using the economic methods developed in the field of *industrial economics* in particular. These methods are related to three different theoretical approaches. The first one originates from the classical approach and the triptych "Structure-conduct-performance" introduced by J. Bain in 1959 following work by Robinson and Chamberlain. When applied to the fisheries industry as a chain of activities, it raises questions related to competition in sea product markets, technical change and its effects, the strategic behaviour of the actors involved and the nature of the relationships between buyers and suppliers at each stage of the chain and also to the profitability of the various activities along the chain. The second theoretical approach, originating from the neo-classical approach has developed from the theory of imperfect competition and games theory. Its application to fishery-related industries raises problems relative to the characteristics of the product (such as quality, differentiation, compatibility...), the business (existence of networks, of cooperation...) and the markets so as to define interaction models between the businesses in the sector. And finally, the last theoretical approach originates from the organisation theory of Coase and Alchian and deals with the conditions related to the organisation and the growth of businesses, the nature of capital and the behaviour of those involved in the business.

Besides the industrial dimension, the clear acceleration of events responsible for fishery globalisation in the last ten years speak in favour of a more systematic approach to the *theories of international economics*. Some of these events are the development of international trade in sea

*l'économie internationale.* Parmi ces phénomènes, on peut noter le développement du commerce international de produits de la mer, la multiplication des investissements internationaux dans les industries de la pêche et de la transformation ou encore les accords internationaux réglementant l'accès aux zones de pêche et aux marchés. Les questions soulevées se réfèrent alors aux opportunités et aux enjeux liés à l'internationalisation des échanges de produits de la mer, à l'analyse des investissements internationaux au sein de la filière pêche et des industries dérivées et aux effets des politiques commerciales sur leur développement.

Enfin, *l'exploitation d'une ressource naturelle renouvelable* confère à la filière un caractère singulier qui impose la prise en compte du caractère aléatoire de l'offre et des impératifs de gestion des stocks naturels, afin de pérenniser les activités économiques qui en dépendent. Ainsi d'un point de vue économique, de fortes contraintes d'approvisionnement en aval de la pêche jointes à des micro-marchés très interdépendants pèsent à la fois sur l'ajustement des capacités de production et leurs conditions d'utilisation, et par effet direct sur la satisfaction d'une demande finale croissante des consommateurs.

La conjugaison de ces trois champs d'analyse provoque l'émergence de nouvelles problématiques se rapportant à l'interprétation des faits économiques observés dans le secteur de la pêche et de ses industries connexes. A titre d'exemple, la question de la formation des prix à différents stades de la filière ou l'analyse de la concurrence entre produits carnés et produits de la mer sur les marchés de consommation relèvent de cette combinaison d'approches théoriques. De même, la réflexion menée sur le thème du commerce international de produits de la mer au regard des structures de marché imparfaites qui prévalent actuellement dans la plupart des pays peut s'enrichir de la fertilisation croisée des concepts développés en économie industrielle et économie internationale depuis plus d'une dizaine d'année.

La référence simultanée à ces trois domaines importants de la pensée économique ouvre de larges perspectives pour l'analyste soucieux de mieux comprendre les phénomènes économiques inhérents à l'exploitation, la transformation et la commercialisation des produits halieutiques. La session présentée ici illustre cette filiation commune des problématiques, même s'il est frappant de constater la diversité des thèmes et des approches retenus par les auteurs. De façon synthétique, trois thèmes émergent de l'ensemble des contributions. L'analyse de la contrainte d'approvisionnement du secteur de la transformation des produits de la mer est abordée par J.M. Young & J.F. Muir dans le cas du Royaume-Uni,

products, the multiplication of international investment in fishing and processing industries and also international agreements regulating access to fishing areas and markets. The questions raised relate to the opportunities and threats of the globalisation of trade in sea products, to the analysis of international investments within fishing and secondary industries and to the effect of trade policies on their development.

Finally, the *exploitation of a renewable natural resource* gives the chain a particular character wherein the random feature of supply and the need to manage natural stocks must be taken into account so as to ensure the sustainability of dependent economic activities. So, from an economic point of view, the important supply constraints downstream from the fishery together with strongly interdependent micro-markets weigh heavily on both the adjustment of productive capacities and their conditions of use and directly on the satisfaction of the growing final consumer demand.

From the combination of these three fields of analysis new problems emerge concerning the interpretation of economic facts observed in the fishing sector and its related industries. For instance, the problem of price formation at different stages along the chain or the analysis of the competition between meat and sea products on consumer markets is related to this combination of theoretical approaches. In the same way, all work on international trade in sea products in the context of imperfect market structures presently prevalent in most countries could benefit from mixing concepts which have been developed in industrial and international economics over the last ten years or so.

Reffering simultaneously to these three important fields in economic thought opens promising prospects for the analyst who wishes to improve his understanding of the economic phenomena inherent in exploitation, processing and marketing of fisheries products. This session illustrates the common ground underlying the problems even though the themes and the approaches of the different authors vary a great deal. In summary, three main themes emerge from the contributions. Analysis of the supply constraint to sea product processing sector is presented by J.A. Young & J.F. Muir in the case of the United Kingdom and M. Deme & M. Bakhayokho in the case of Senegal. The second theme, the problem of substitutability of sea products for other products on the final goods market is the subject of two papers by T. Naito & al. and by T. Vukina & J.L. Anderson. The final theme concerns the study of the causes and effects of imperfect market structures with contributions by L. Temri and S. Cruz.

In the first theme, J.A. Young and J.F. Muir develop their analysis of the processing sector with respect to the

M. Deme & M. Bakhayokho dans le cas du Sénégal. Le second thème, la question de la substituabilité des produits de la mer vis-à-vis d'autres produits sur les marchés de biens finals fait l'objet de deux contributions par T. Naito et al. et par T. Vukina & J.L. Anderson. Enfin, le dernier thème concerne les études des causes et des effets des structures de marchés imparfaits avec les apports de L. Temri et S. Cruz.

Dans le premier thème, J.A. Young et J.F. Muir développent leur analyse du secteur de la transformation au regard des différents événements institutionnels passés qui ont affecté le niveau des apports nationaux sur le marché britannique : accession du Royaume-Uni au Marché Commun en 1973, extension des Zones Economiques Exclusives en 1977, instauration de la Politique Commune des Pêches en 1983 ... Les auteurs confrontent la chute des débarquements territoriaux avec l'évolution des structures du secteur de la transformation et celle de la consommation de produits de la mer. Ils en tirent des conclusions sur le manque de perspectives de développement et la fragilité du secteur de la transformation au Royaume-Uni. M. Deme et M. Bakhayokho examinent quant à eux les potentialités d'approvisionnement de l'industrie sénégalaise grâce aux apports de la pêche artisanale. Ils en estiment les effets sur la stratégie des entreprises locales, notamment à l'exportation et soulignent les mesures institutionnelles qui encadrent l'ensemble de la filière. Les recommandations des auteurs vont dans le sens d'une nécessaire redistribution des subventions publiques sur l'ensemble de la filière afin de privilégier la commercialisation locale des produits.

Pour le second thème, les méthodes et les applications illustrées par les deux communications sont encore une fois très différentes. T. Naito, R.S. Johnston et A.L. Shriver traitent de la substituabilité des produits de la mer et des produits carnés (volailles et autres viandes) à travers deux modes de commercialisation distincts : la restauration et la grande distribution. Le modèle théorique vise à comparer les effets des prix relatifs et du différentiel de qualité de ces produits sur le comportement des consommateurs finals. Les auteurs souhaitent tester empiriquement leur modèle afin d'identifier les facteurs qui affectent la consommation des produits de la mer au regard de différents circuits de distribution. Dans un autre registre, T. Vukina et J.L. Anderson analysent la nature des liens existant entre les marchés de la farine de poisson et du soja, où est présent le même acheteur : l'industrie de l'alimentation animale. Le but de leur modèle, basé sur des séries temporelles, est d'établir des prévisions de prix sur ces marchés afin d'orienter la stratégie des entreprises de production de farine de poisson, compte tenu de la substituabilité de ces produits vis-à-vis des autres aliments protéiniques pour animaux.

different institutional events that have affected the level of national supply on the Bristish market: accession of the UK to the common market in 1973, extension of the EEZ in 1977, setting up of the Common Fisheries Policy in 1983... The authors compare the fall in territorial landings with the evolution of the structures in the processing sector and consumption of sea products. Conclusions are drawn about the lack of prospects for development and the weakness of the processing sector in the U.K. M. Deme and M. Bakhayokho examine the possibilities of supplying the Senegalese industry from artisanal fishery catches. They assess the effects on local business strategy in particular on the export side and underline the institutional framework within which the chain operates. The authors recommend a redistribution of government subsidies to the whole of the chain so as to develop local marketing of products.

In the second theme, the methods and the applications illustrated by the two papers are once again very different. T. Naito, R.S. Johnston and A.L. Shriver deal with the substitutability of sea and meat products (poultry and other meat) through two different modes of marketing: catering and wholesaling. The theoretical model aims at comparing the effects of relative prices and differential quality of these products on consumer behaviour. The authors wish to test their model empirically so as to identify factors affecting sea product consumption with regard to different distribution circuits. For their part, T. Vukina and J.L. Anderson examine the nature of the links between the markets concerned with fish and soya meal where the same buyer is present: the animal food supply industry. Their model, based on time series aim to establish price forecasts on these markets so as to guide the production strategy of fish meal businesses, taking into account that these products can be substituted by other proteinic animal foods. The results obtained tend to validate the use of such dynamic models where forecasting can help processors adjust their strategy according to expected prices.

The last group of papers is probably the most heterogeneous as the authors consider both the effects and the causes of imperfect competition on the sea product market. L. Temri deals with the relationship between innovation and technical change in sea product processing industries, a subject that has so far been little dealt with by fisheries economists. In particular, the authors considers the possibilities of improvement in the French processing industry – in terms of productivity gains or increased flexibility..., possibilities linked to the integration of new methods in the production process. Empirical results seem to show that these methods are underused compared to other economic sectors. In a conceptual then empirical fashion, S. Cruz studies the monopolistic

Les résultats obtenus tendraient à valider le recours à ces modèles dynamiques dont la capacité prédictive peut permettre aux transformateurs d'ajuster leurs stratégies en fonction des anticipations de prix relatifs.

Le dernier groupe de contributions est peut-être le plus hétérogène dans le mesure où les auteurs traitent à la fois des causes et des effets de la concurrence imparfaite sur le marché des produits de la mer. L. Temri aborde un aspect jusqu'ici peu exploré par les économistes des pêches c'est-à-dire les enjeux de l'innovation et du changement technique dans les industries de transformation des produits de la mer. L'auteur s'interroge notamment sur les potentialités d'amélioration de l'industrie française de transformation – en terme de gains de productivité ou de flexibilité accrue ... –, liées à l'intégration de procédés nouveaux dans le processus de production. Les résultats empiriques sembleraient témoigner d'une sous-utilisation de ces procédés comparativement à d'autres secteurs économiques. S. Cruz examine, sous un angle plus conceptuel d'abord et plus empirique ensuite, le pouvoir monopolistique de certaines entreprises portugaises, impliquées tant dans la production que dans le négoce ou la transformation et qui seraient à l'origine d'une croissance des prix à la consommation plus rapide que celle des prix à la production. Les deux contributions de cet auteur soulèvent notamment la question du rapport existant entre des structures de marché imparfaites et la nature du commerce international de produits de la mer à partir de l'exemple de l'industrie portugaise. Selon l'auteur, le pouvoir oligopsonique de quelques compagnies constituerait une entorse aux articles 85 et 86 du Traité de Rome relatifs au respect de la concurrence et pénaliserait les acteurs économiques de moindre poids. De ce constat, l'auteur tire quelques recommandations sur les choix de politiques économiques à adopter afin de réduire le différentiel de prix entre la production et la commercialisation de produits halieutiques.

L'analyse dynamique de la concurrence telle que l'a synthétisée M. Porter semble être un des vecteurs communs aux travaux présentés à l'occasion de cette session. Si les relations entre clients et fournisseurs ainsi que l'analyse de la substituabilité des produits ont été abordées et méritent une exploration plus systématique, quelques perspectives de recherche se dégagent dans le champ de l'économie des organisations, encore peu considéré dans le cas du secteur des pêches. Ainsi, le rôle croissant des pouvoirs publics – qui agissent à la fois comme acteurs et comme élément structurant du système – affecte le comportement de l'ensemble des acteurs et mérite à ce titre qu'on lui accorde une part plus importante des efforts de formalisation. Il apparaît également que, depuis environ une décennie, les secteurs de la

power of some Portuguese businesses dealing with production as well as trade and processing which are the cause of a faster increase in retail prices than in dockside prices. This author's two contributions raise more specially the issue concerned with the relationship between imperfect market structures and the nature of international trade in sea products taking the Portuguese industry as an example. According to the author, the oligopsonistic power of some companies is an infringement of articles 85 and 86 of the Treaty of Rome concerned with ensuring competition and penalizes lesser economic actors. From this statement, the author drawn some recommendations about the choices of economic policies to be adopted so as to reduce the difference in prices between production and marketing of fishery products.

The dynamic study of competition as synthesised by M. Porter appears to be one common element in all work presented during this session. If relationships between buyers and suppliers as well as the analysis of product substitutability have been examined and deserve a more systematic approach, research projects have emerged in the economics of organisation so far seldom applied in the case of the fishery sector. In the same way, the growing role of government – acting both as a player and a structural element in the system – affects the behaviour of all the actors and so deserves a more important role in the rorizing. It also appears that for about the last decade processing and distribution sectors have built increasingly closer ties with the companies responsible for funding, research and development, and marketing. The orizing about competitiveness in "non cost items› and taking into account intangible investments in the analysis of actors downstream from the fishery chain are hence justified. In the same way, the strong interdependencies between actors in the system on a world scale, induced in particular by the weight of supply constraints, highlight a field of study to be examined with questions about capital movements or technology transfer between countries.

The contributions in this session are therefore an encouraging step towards better economic understanding of the complex working of the fishery-related industries.

transformation et de la distribution tissent des liens de plus en plus étroits avec des sociétés de service assurant des fonctions de financement, recherche-développement ou marketing. La réflexion en terme de compétitivité dans le domaine du « hors-coût » comme la prise en compte de l'investissement immatériel dans l'analyse des acteurs en aval de la filière pêche trouvent ainsi leur justification. De même, les fortes interdépendances entre les acteurs du système à l'échelle mondiale induites notamment par le poids des contraintes d'approvisionnement éclairent un champ d'analyse à prospecter, avec des questions portant sur les mouvements de capitaux ou les transferts de technologie entre pays.

Les contributions de la présente session constituent donc un pas encourageant vers une meilleure compréhension économique du fonctionnement complexe des industries dérivées de la pêche.

# UK Fish Processing Industry Strategies: From the CFP Decade to the Single Market

**James A. Young[a] and James F. Muir[b]**

[a]Department of Marketing, University of Stirling, Stirling, FK9 4LA, Scotland

[b]Institute of Aquaculture, University of Stirling, Stirling, FK9 4LA, Scotland

ABSTRACT

*Within the EC there is growing concern at the increasing trade deficit in fish products. Apart from the trade balance issue, this deficiency is also significant because it implies some failure of the fish processing industry to adopt strategies generating additional benefits from fishing. As a major producer within the EC, the case of the UK is presented. The paper provides a contemporary analysis of the UK fish processing sector, primarily from a marketing perspective.*

*The paper begins with a retrospective analysis of the changes, and their significance, in the UK fish marketing environment. It is argued that many of the contemporary problems experienced within the processing sector are attributable to the failure of the EC Common Fisheries Policy (CFP). The supply side difficulties thereby engendered have resulted in decline and have precluded possible expansion of the sector at a time when the market for fish has become more buoyant.*

*Whilst past commentary on the CFP's failure has been focussed primarily upon the catching sector, comparatively little attention has been given to the onshore sector. This analysis thus incorporates some of the findings of a more recent investigation of the UK onshore sector which reveals the more widespread impact of the CFP's failure.*

*However, it is argued that decline is not attributable solely to the CFP; other policy measures too have been ineffective in surmounting processors' problems and, in some cases, have made the current situation worse. The paper latterly appraises the strategic implications for the UK industry in the future marketing environment of the single market.*

*The paper concludes that if the UK fish industry is to enjoy the opportunities of the single market there is a need for fundamental policy review. In particular it is argued that future fisheries policy should take more explicit account of the interdependence of the industry's sectors and particularly that of the onshore sector. Such an approach should go some way towards improving future EC fish trade deficits and increase the socio-economic benefits derived from the fish industry.*

## 1. INTRODUCTION

The aim of this paper is to present a contemporary analysis of the UK fish processing industry, primarily from a marketing perspective. The UK has been chosen as reflecting present events in the fish industry in many other EC member states. As elsewhere, the UK processing sector is currently beset by a number of critical factors which pose a significant threat to its future. Resolution of these issues will be essential if the industry is to profit from changes in the market for fish.

Somewhat ironically, these difficulties have come at the very time of increasing opportunities for the industry, due to a resurgence in demand for fish and the impending formation of the single market under the terms of the 1987 Single European Act (SEA). Put simply the industry continues to suffer from the effects of a level of fishing effort in excess of available resources. Although this has been widely accepted by the industry and related organisations for many years, the regulatory instruments imposed under the Common Fisheries Policy (CFP) are unanimously acknowledeged to have failed in their objectives of alleviating the situation (Cunningham & Young, 1983; Toerring, 1991).

We begin by presenting an assessment of the contemporary evolution of the industry, its supplies and the market for fish. After an overview of the processing sector's key characteristics, we next consider the impact of the various changes described. The analysis concludes with comments on the likely future responses of the processing sector, and the implications for the sector and for the fishing industry as a whole. Data is drawn from a series of face-to-face and postal interviews conducted with a representative sample of processing firms over the past year.

## 2. THE UK FISH INDUSTRY

The roots of the contemporary difficulties within the UK processing industry are complex but may be traced to events prior to the 1983 agreement of the CFP. In particular, the historical dependence of the UK industry upon distant water fisheries was severely curtailed by the Cod Wars with Iceland, and the 1977 international adoption of 200 mile EEZ's. Although the extension of EEZ's might have increased indigenous fishing opportunities, this did not materialise, because of the UK's earlier membership of the Common Market in 1973. In spite of accounting for around two-thirds of the EC sea area at the time, fishing opportunities were pooled along with the eight other member states. Under the subsequent 1983 agreement, a Total Allowable Catch (TAC) quota allocation system was formalised giving the UK 35.8 % of the seven major species. This agreement was intended to run for 20 years, subject to the mid-term review of 1992. Notwithstanding the outcome of the review, the combination of events has had a marked impact upon the UK industry.

## 3. TRENDS IN UK INDIGENOUS FISH SUPPLIES

The data on indigenous fish supplies shown in Figure 1 provide a starting point in identifying the significance of these changes. This shows a decline in the quantity of fish landed by British vessels; a fall of more than 40% in UK fish landings by volume between 1973 and 1990. In recent years supplies have also become more volatile; the 1991 figure, 0.59m tonnes, represents a decline of more than 25% over only four years.

The new regime of the fisheries sector is reflected not only in terms of reduced indigenous fish supplies, but also in the sub-national share of landings. As shown in Figure 2, Scotland's share of UK fish landings has risen dramatically to around 75%, whilst that of England and Wales, especially in the former distant water ports, has fallen in both absolute and relative terms.

The implications of these changes for the processing sector are considerable, given its development and its traditional reliance upon local supplies. As a raw material, fish is highly perishable and commonly yields less than 50 % finished product. These factors, *inter alia,* have favoured a raw-material-orientated (ie fishing port) location for the industry. Changes in quantity and location of fish available have been further compounded by the changing composition of

supplies, as shown in Figure 3. Cod and haddock, the most favourably received by the UK market, have experienced the greatest shortfall, and since 1987 the situation has worsened progressively, despite a slight increase in the 1992 North Sea haddock quota. Thus in 1990 TAC's for cod and haddock were reduced by 17% and 33% respectively.

To some extent the long-term decline in landings has been offset by an increase in quantity of pelagic species, notably mackerel and herring, although these too have witnessed periodic supply shortfalls. Pelagic species are in any event less preferred by UK consumers and they command a lower market price. Whilst in recent years, the domestic pelagic market has been usefully countered by large volume exports to the former Eastern bloc, the political and economic reforms therein have cast considerable doubt on future trade opportunities.

Some respite to indigenous supply deficiencies might be noted from aquaculture sources; from trout, shellfish, and in particular from the dramatic expansion in farmed salmon production. Over the last two decades this last sector has reached an output estimated to be worth more than £140 million. From 10,000t in 1980, 31,000t were produced in 1989, and 32,350t in 1990. This compares with salmon fishery landings of some 400-500t. There is evidence of substantial change in processing and distribution in servicing this sector, with both traditional and more recent industry participants (EAFE, 1990) However the growth of the sector is constrained by production cost, by site availability and by market development, and current assessments forecast modest growth or even contraction, in both the trout and salmon sector. While diversification into alternative higher value species is actively being pursued, technical difficulties continue to exert a substantial constraint. Even given favourable conditions, it would clearly take significant time before anything approaching the range and volume of the capture fisheries could conceivably be substituted. In the short run it is therefore likely that attempts to remedy the increasing deficiency in those indigenous supplies preferred by the UK market will continue to depend upon the international market.

## 4. TRENDS IN UK TRADE IN FISH

For the purposes of this paper, UK trade in fish is confined to volume data; the value of trade generally reflects similar trends, albeit more complex due to exchange rate fluctuations. Imports have increasingly been used to satisfy rising demand and by 1990 these accounted for over 50% of supplies for human consumption. The overall growth in the quantity of fish imported is shown in Table 1.

Given the variations in supply elsewhere, and relative currency movements, this general trend of increased imports contains significant counter-trends. For example, whereas imports of fish to the UK increased by 14% between 1988 and 1989, they fell back 4.5% by 1991. The most recent data for the first quarter of 1992 shows an increase of 7.1% over the corresponding period in 1991 (SFIA, 1992). Despite such temporal variations, in the absence of more stable indigenous supplies, the UK processing sector is more dependent than ever upon the international market and its attendant exchange rate movements.

Closer examination of the data also shows that imports have increasingly been in the form of processed product rather than raw material. This precludes to the UK fish industry the opportunity to add value and to enjoy associated benefits of income and employment multipliers. This is especially significant in view of the high dependence upon the fisheries sector in certain regions. Furthermore the benefits foregone have largely been to non-EC countries; Figure 4 shows these to have been the major source of the increased quantity of imports.

Although imports from other member states have remained relatively constant at levels around 100,000t - 150,000t, the EC has become increasingly important for UK exports. Over the 1980's, their volume has increased by 87%, with France being the principal recipient; aquaculture, particularly that of salmon, is a contributor to this trend. Indeed since 1986 the UK has moved to a position of a small trade surplus in fish with other EC members.

However, from 1983 this internal surplus has been more than offset by a widening trade deficit with non-EC countries. For example, in the late 1980's over 70% of cod and over 80% of haddock came from non-EC sources. Comparison of the overall UK trade balance with those of other EC states is complicated by the vagaries of compiled data. However, data does suggest that only Denmark, Ireland, and in most years the Netherlands, have positive trade balances in fish, whilst the UK's deficit is only regularly exceeded by that of Germany (Eurostat, 1991). Having thus determined something of the UK's international market, we now consider the domestic market.

## 5. TRENDS IN THE UK MARKET FOR FISH

Estimates of the UK market for fish in 1990 range between £1,600M (Leatherhead Food RA, 1991) and £2,260M (Marketing Strategies for Industry, 1992). The market is split fairly evenly between consumption in the home and that in various catering market segments. Table 2 below illustrates the trend in household consumption in terms of the total quantity consumed and the share of household food expenditure spent on fish.

The data show that since the mid-1970's, household consumption of fish has generally increased; by the end of the 1980's almost 16% more than in 1975. More significantly, fish consumption has shown a consistent improvement in terms of the share of household expenditure on all foods; in 1989 and 1990 fish accounted for 5.5%, compared to only 4.5% in 1980. Compared with 1960 and 1955, when fish accounted for only 4.4% and 3.7% respectively, it would appear to confirm that consumers now place a higher value on fish as a foodstuff.

This is also reflected in relative price movements. Since the mid-1980's, fish prices have increased at a rate in excess of other foods, yet volume consumption has remained surprisingly strong. This may be partly attributable to favourable exogenous influences on the fish consumer, and increased concern with health attributes in food may be particularly important. Fish is increasingly perceived as a healthy foodstuff which may confer benefits not offered by many competing substitutes. This perception is further reinforced by increasingly adverse attitudes to traditional alternatives, notably red meat. Evidence also suggests that many of the negative perceptions of fish, such as being difficult to prepare, bony, malodorous and lacking in variety and satiety are diminishing (Mogan, 1990). A further influence involves the increasing interest in variety, and a gradually widening acceptance of non-traditional species. In the UK, some part of these improvements may be attributed to the generic promotion of fish undertaken by the Seafish Industry Authority (SFIA) since the 1980's.

The form of fish consumed shows significant change. Since the 1970s, consumption of fresh fish has declined, although some redress in the trend is now evident. Frozen fish consumption has increased, reflecting a growth in preferences for convenience attributes in foods due to change in social and domestic circumstances. Canned fish and shellfish have also become more popular, and markets for aquaculture products, particularly various forms of trout and salmon have been substantially increased. Many of these changes reflect developments in the food retailing environment. The growth of MROs (multiple retail outlets) has ensured that the products stocked reach a larger number and wider range of potential consumers. MROs have traditionally been dominant in the frozen and canned fish sectors, typically accounting for over three-quarters of the retail fish market. More recently however they have made substantial gains within the fresh sector and the current market share of 32% (SFIA, 1992), can be expected to increase further still. This evolution reflects the trends of other competing foods established earlier in MROs.

Given this overview of both ends of the UK fish marketing chain we now consider the fish processing sector in further detail.

## 6. SOME KEY CHARACTERISTICS OF THE UK PROCESSING SECTOR

The Grampian (NE Scotland) and Humberside (E England) regions hold the principal concentrations of fish processing activity within the UK, although significant units are also found in other locations. This distribution reflects the regional concentration of the fishing fleet, although Humberside is now more important in fish processing than it is in respect of fishing capacity. This imbalance results partly from the dramatic decline of the distant water fishing opportunities formerly prosecuted by Humberside interests, but is also explained by the co-existent location of major firms with both fish and non-fish food interests. Grampian, the other major concentration of firms, accounts for around one-third of all UK processing jobs, and contemporary developments suggest that it may become a more dominant force in fish-specific food firms. Against this background however, there are very real concerns for the future structure of fish processing. In particular, many of the smaller-scale firms, and those which are no longer located near major supply sources, are at risk of closure. This may lead to marked change in the concentration of ownership and the distribution of activity.

In terms of the size of the processing sector, surveys in the 1980s identified around 1,000 UK companies, with up to twice this number of plants (Young, 1986; Banks, 1988). A more recent study estimated over 1,400 sites, in which a smaller number of firms operated (Dunn, Potten & Whitmarsh, 1991). The industrial structure of the processing sector is

characterised by a comparatively small number of large organisations and very many small firms. Estimates suggest that around 75% of the firms involved employ 10 or fewer people, whereas those employing more than 100 account for less than 4% of all firms.

Within the sector, operating costs have increased and are manifest in a general downturn in profitability. Results of a recent internal EC investigation found a decline in the return on capital invested from 17.9% in 1988 to an estimated 7% in 1990 (Scotland on Sunday, 1991). Similarly, growth in the value of output decreased from 9.6% in 1988 to an estimated 6% in 1990; whilst employment fell by 9.8% in 1989 and 8% in 1990 (Ibid). More recently, further closures have been announced, including a major branch plant of Findus in Grimsby, and the withdrawal of Geest from MacFish in Fraserburgh (Fishing News, 1991). Some indication of the local significance of such events is reflected in the estimate that the Findus closure alone will raise by 10% the total unemployed in the Grimsby travel-to-work area (Great Grimsby Borough Council, 1991).

Having considered some of the more salient features of the processing sector the next stage of the analysis requires some perspective on the impact of the forementioned changes within the fish marketing environment.

## 7. TRENDS IN THE UK FISH PROCESSING SECTOR

A notable consequence of increased volatility within indigenous supplies has been a rise in prices, tighter operating margins and greater reliance upon the international market. However the international market has also witnessed shortfalls in supplies, reinforcing the effects of domestic constraints. In the case of haddock, whose 1990 North Sea TAC was only 28% of that in 1988, the 1990 UK quayside price rose by 40% while the corresponding increase at the retail level was only 13% (Milne, 1991). Apart from the short run difficulty caused by such internal market price increases, these higher price levels will also drive up the future minimum prices of imported supplies upon which the EC industry is increasingly dependent.

This scenario results from the mechanism of the CFP Marketing Policy which determines annually a Guide Price for eligible species on the basis of their internal market prices over the preceding three years. The Guide Price in turn is used to set an Official Withdrawal Price (OWP) which acts as a floor price on the internal market, and a Reference Price (RP) which sets a theoretical minimum price for fish imports. Thus the 40% haddock price increase of 1990 will act to raise the RP for the period 1991 - 1993. Even if the TAC reductions which influenced the increase in internal prices, were effective in stock recovery and so permitted higher TACs to be set, thereby reducing pressure on internal prices, the price of imports would still reflect the higher levels established during the earlier period of shortage. Given the extent of processors' import dependence, this lag effect may then result in increased raw material costs in the internal market for the first year and, assuming an internal supply recovery thereafter, in increased price for external supplies for the following three years .

Moreover, any tendency for internal equilibrium prices to fall as a result of increased TACs will also be tempered by the existence of the OWPs. Therefore internal market floor prices too will exhibit the same lag effect; that is, high fish prices in any one year will tend to raise minimum prices for the subsequent three year period.

It may be argued that political considerations also come into play in determining the exact level of Guide Prices and thus their derivatives, RPs and OWPs. However significant deviations from the basis of determination, as laid down in the CFP, are likely to affect adversely both fish producers or buyers at various times; thus leaving comparatively little room for political compromise. This mechanism is important not only in terms of its cost (and revenue) implications. More fundamentally, it illustrates the complex interdependence of resource management policy and the market, and the risks of localised distortions and unintended disbenefits.

The impact of this lag effect will also be influenced by the speed of stock recovery. A near instantaneous recovery would produce the effect described above, whereas a more gradual recovery over several years would tend to reduce the differential between internal and reference prices, but not necessarily external equilibrium prices. In addition a more prolonged stock recovery would extend the related marketing costs of continuing supply shortfalls.

Shortfalls in supply are likely to remain an endenic feature for the foreseeable future. Although both the industry and Government now accepts the need for a reduction in fishing effort, 30% being recommended by the International

Commission for the Exploration of the Sea (ICES), the UK Government has failed to reach agreement with industry about how to achieve such reductions. Instead, it has relied upon a mixture of stricter technical conservation measures applied both unilaterally and by the EC.

The principal new measures applied, often against the advice of the industry (Allan, 1991), have included a restriction on days at sea and increased net mesh sizes. These have profound implications for the industry's ability to respond to existing and new market opportunities. Days at sea legislation has resulted in discontinuity of supply, contrary to the CFP objective of ensuring market stability. There is also reason to doubt its effectiveness in reducing effective fishing effort, as boats fish all the harder to compensate. Yet currently the UK Government seems intent on relying more on this measure in future. The increase in net mesh sizes, at least in the short run, will reduce the supply of certain marketable fish and begs numerous questions about the future of fish conservation, not least due to interaction in multi-species fisheries. This is especially significant in the context of the North Sea (Armstrong, 1991). More immediately, the measures will create yet further turbulence in the supply of demersal species upon which a number of processing firms, and related marketing channels have been established.

Although much of the political debate has focussed around the more immediate impact on the fishing fleet; clearly the processing sector is critically, and no less, dependent upon solutions to the EC's resource management problems. Resolution of these issues is a prerequisite for the future welfare of the processing sector. The EC would seem to accept the desirability of this, as is reflected in some aspects of policy implementation. For example, the EC has been active in providing financial assistance to firms to upgrade the marketing of fish products under the terms of Regulation 355/77 and its subsequent revision in Regulation 4042/89.

More controversially, the EC also has sought to make uniform, and to upgrade, standards of hygiene in the fish marketing chain, in an attempt to promote the longer term ability of the industry to compete within the market for foods. At the same time, uniformity of standards should preclude the free-trade caveat of Article 36 of the Treaty of Rome which permits trade barriers for reasons of hygiene. In the past this has been used more for reasons of national protectionism rather than concern with health and safety. The EC perceives that common hygiene legislation will generate economic benefits and ensure fair competition in intra and inter-Community trade (Daelman, 1989). Such moves are seen as a vital corollary to the single market.

However, these proposals have not met with universal approval. In the context of this paper the proposals are significant more for their broader implications, rather than the anomolies in the details which have been reviewed elsewhere (Maddock and Young, 1990). The imposition of the new legislation from 1993 will require many organisations to undertake investment at a time when they are perhaps least able to afford to do so.

Such measures may well be justifiable if there were grounds to suggest that fish was presently a danger to public safety; but evidence, at least for the UK, does not support this view. Thus in comparison to poultry, fish has been found to be a far less significant source of food-poisoning incidents reported in the UK (Hayes, 1989). The introduction of further quality standards generally imposes some further cost, borne by the industry and ultimately the consumer. So long as an appropriate standard of safety is being attained, it is arguable that firms should be free to determine the incremental quality attributes which they build into their products and for the level demanded by their target markets.

This "broad brush" approach is likely to have a profound impact upon the socio-economic welfare of EC and third country regions which are typically highly dependent upon fish. Evidence from within the UK industry during this present time of heightened uncertainty suggests that rather than make such investment, some firms will instead simply opt to leave the industry. In the absence of additional support, *ceteris paribus*, this trend may lead to a substantial decline in the number of plants and an attendant increase in concentration of ownership . There is every likelihood that there will be fewer firms around to enjoy any benefits to be had in the single market.

Having identified some of the more general trends surrounding the industry, it remains to consider the more likely responses of firms to the changes within their marketing environment. Given the multitude of decision making units present, comments necessarily run some risk of generalisation. Notwithstanding this caveat, the responses may be assessed in terms of their basis in supplies/ products and markets.

## 8. SUPPLIES, PRODUCT AND MARKET ORIENTATED RESPONSES

The fundamental nature of the changes in fish supplies has clearly had a profound impact on the procurement policies of most processing firms. Firms have become much more diverse in sourcing product and in some areas this has resulted

in a dramatic decline in the extent of dependence on local supplies. In the case of Humberside, many of the secondary processors report receiving less than 10% of their supplies from England and Wales. However, in the case of smaller firms with lower volume throughput such options are not viable and here reliance is placed upon the collective ability of port markets to attract supplies; an option with its own restrictions.

In some cases the more immediate problems of increased raw material costs have been alleviated to an extent by strategies of adding value and of product range extensions based on farmed, pelagic and other species. But such alternatives are not without their problems. There is evidence to suggest that firms are more diverse in the range of individual species processed, but given that most firms primarily process demersal species there are inherent constraints in terms of regularity and quality of supplies available, and their market acceptability. Moreover, many of the readily available alternate demersal species tend to command premium prices on the export market in the whole, fresh form, thus leaving little opportunity for species substitution.

Diversification into pelagic species tends to demand a fairly large scale investment, given the need to process large volumes of low unit value, often within a restricted time period. Moreover, the more capital intensive plant also tends to be more species specific. Whilst there have been some notable innovatory developments in this sector in recent years, significantly with vertical links in catching, it remains the case that pelagics have a somewhat restricted market appeal. It is therefore likely that pelagic species will tend to remain the preserve of a comparatively small number of firms. Within the shellfish sector, the market overall has warranted continued growth although much of this has rested upon imported supplies of a comparatively small range of species, and much of the recent increase in diversity in locally caught species has served the traditional fresh markets in mainland Europe.

The increasing availability of aquaculture supplies, particularly rainbow trout and salmon, but also mussels, oysters, and scallops, has offered opportunities for some processors, notably in smoking and portion pack development, and in specialised export products. While some of the traditional sector has participated successfully, a substantial part of this growth has come through new entrants to the sector specialising in aquaculture products, and developing their own distribution systems in conjunction with MROs, and with European wholesalers. This sector can be expected to continue its growth albeit at a reduced rate, as it now shows signs of restraint through increased international competition, through increasing site regulation, and through decreasing profitability of production enterprises.

The tighter operating margins experienced by processors have encouraged attempts to pass on price increases down the marketing chain. The ability to do this however has been constrained by the greater and growing power of the multiples and, consumer resistance to fish prices rising at a rate in excess of other competing foods. Throughout the 1980s processors dealt with this problem by adopting strategies of "adding value". Within some market sectors at least this was often interpreted as adding as much non-fish ingredient as could be incorporated. Whilst there undoubtedly remains scope to add value by way of incorporating further product attributes valued by consumers, it may increasingly be the case that the attributes so valued are less tangible, more sophisticated and difficult to incorporate.

In spite of the many internal and external problems involved in satisfying market demand, the overriding opportunity must be seen as the existence of a strong and growing market for fish. In addition to growth within the domestic market, the wider prospects of the single market loom. By any standards the aggregate market potential of 340 million consumers created by the SEA and subsequent expansion of the EC is considerable. However much uncertainty exists as to whether such goals are attainable. Irrespective of what new opportunities are created, and in spite of improved supply through the aquaculture sector, the whole industry's ability to exploit them is critically dependent on the stabilisation of resource management. This in itself may require no lesser political will than that necessary to agree the SEA. But certainly, from the fish industry's perspective, it is a vital condition.

## 9. CONCLUSION

In the absence of an improvement in supply there can be little reason to believe that the UK processing sector will become a much more competitive force within the EC market for food. The prospect is more likely that even greater dependence will be placed upon imports from third country firms eager to supply the growing demand for fish in the single market, and eager themselves to add value at the source of supply. An exception to this trend might be found in the aquaculture sector, where local conditions provide good prospects for quality supply. However this in turn will also

be vulnerable to competitive trends at the international level, and is in any event unlikely to match the capture sector in scale. From the perspective of the UK fish industry it is thus believed that the key to the potential benefits of the SEA lie more immediately within the sea than within the single market.

ABSTRACT

*It is often said that the small-scale fishing is meant to cover food needs of local populations whereas fishing caters for exports. However, the difficult situation in which many large scale fishing companies are as a result of too low revenue to cover high operating costs, insurance premiums and depreciation of their equipment has forced many industries to turn towards artisanal fishermen to supply their plants with raw materials. This paper analyses this new experiment and tries to measure its consequences on the level of the local consumption, exportations, fishing effort and the different types of fishing.*

RÉSUMÉ

*On a souvent tendance à avancer que la pêche artisanale est essentiellement destinée à couvrir les besoins alimentaires des populations du pays alors que la pêche industrielle approvisionne les exportations. Cependant, la situation déficitaire de beaucoup d'armements de pêche industrielle, consécutive à l'insuffisance des recettes pour couvrir les fortes charges financières, les assurances et l'amortissement de l'équipement, a obligé beaucoup d'industriels à se tourner vers la pêche artisanale pour approvisionner leurs usines. Le document se propose d'analyser cette nouvelle situation et tente d'en mesurer les conséquences sur le niveau de la consommation locale, des exportations, de l'effort et des différents types de pêche*

## 1. INTRODUCTION

Les autorités publiques ont souvent tendance à avancer que la pêche artisanale est essentiellement destinée à couvrir les besoins alimentaires des populations du pays alors que la pêche industrielle approvisionne les exportations (MRA, 1991).

Cependant la production insuffisante des armements de pêche industrielle a amené les usiniers à compléter leurs approvisionnements en se tournant vers la pêche artisanale afin d'assurer à leurs usines un volume de production suffisant pour couvrir leurs charges d'exploitation.

Il est très difficile d'estimer la part exacte de chaque sous-secteur dans les exportations de produits de la pêche. En effet, les statistiques officielles, fondées sur les déclarations des exportateurs et les statistiques douanières -lesquelles ne distinguent pas l'origine du produit - ne permettent pas de faire la distinction. Nous avons effectué des enquêtes auprès de 10 usines de transformation et congélation, représentant 70 % du marché et dont les activités sont orientées vers l'exportation. Il en est ressorti que 46 % du volume total de poisson vient de la pêche artisanale. Ce résultat, extrapolé à l'ensemble du secteur, situe à 40 % la contribution de celle-ci. Elle est donc en concurrence directe avec la pêche industrielle dans l'approvisionnement des usines.

Le document se propose d'analyser cette nouvelle situation et tente d'en mesurer les conséquences sur le niveau de la consommation locale, des exportations, de l'effort et des différents types de pêche. Il débouchera sur des recommandations susceptibles de donner à la pêche artisanale sa véritable place eu égard à l'un des objectifs des pouvoirs publics qui consiste en une rentrée massive de devises à travers les exportations de poisson.

La reconnaissance de certaines réalités dans l'approvisionnement des usines exportatrices de poisson doit en effet permettre une distribution plus équilibrée des capitaux disponibles entre les deux sous-secteurs.

En outre, la place de choix qu'occupe la pêche artisanale dans la politique d'auto-suffisance alimentaire lui fait bénéficier de subventions et de détaxes. Toutefois, l'orientation d'une partie de la production de ce sous-secteur vers les marchés extérieurs, couplée à une subvention à l'exportation, ne risquent-elles pas de générer des effets pervers ?.

Face à la dégradation des cours du phosphate et de l'arachide, les pouvoirs publics se sont intéressés à la pêche maritime pour restaurer le déficit de la balance commerciale du pays enregistré depuis de nombreuses années. Partant de l'idée acquise que les usines sont approvisionnées exclusivement par la pêche industrielle, un soutien financier considérable est apporté à ce sous-secteur.

## 2. MOYENS MIS EN OEUVRE

### *2.1 Subventions*

Au Sénégal les subventions accordées à la pêche industrielle sont de deux types : subvention à la production et subvention à l'exportation.

#### 2.1.1 Subvention à l'exportation

Pour stimuler et promouvoir les exportations sénégalaises et maintenir la compétitivité des industries locales sur les marchés étrangers, une subvention à l'exportation a été instituée le 25 août 1980 à titre expérimental pour quelques produits "non traditionnels" tels que les conserves de poisson, les denrées alimentaires et végétales, les engrais etc... L'exportation de ces produits donne droit au versement par le Trésor public de 10 % de leur valeur FOB. En février 1983, cette mesure d'incitation à l'exportation, relevée à 15 % avec une déduction des droits applicables aux matières premières importées, est élargie au poisson frais, transformé ou congelé. Suite à une refonte du système, la loi de 1986 étendait la subvention à l'ensemble des produits halieutiques transformés industriellement et exportés. Un taux de 25 % de la valeur ajoutée industrielle nationale est désormais appliqué. Cette subvention à l'exportation a connu une progression rapide et se chiffre à plusieurs milliards de FCFA de nos jours.

#### 2.1.2 Subvention à la production

Une autre mesure incitatrice dont bénéficie la pêche industrielle est la péréquation faite sur le carburant. Cette péréquation se décompose en :

(i) une subvention indirecte correspondant aux taxes non perçues sur le gazole au bénéfice des bateaux sénégalais et des bateaux basés battant pavillon étranger ;

(ii) une subvention directe supportée par la Caisse de Stabilisation au seul profit des unités de pêche industrielles sénégalaises.

La combinaison de ces deux mécanismes, selon les autorités publiques, devait atténuer les coûts d'exploitation dans le secteur industriel et maintenir le prix du poisson à un niveau ne remettant pas en cause la compétitivité des produits sénégalais sur les marchés extérieurs.

### *2.2 Le crédit maritime*

Les objectifs généraux du crédit maritime, institué en 1981 et dissous en 1989, étaient le renouvellement de la flotte sénégalaise vieillissante, la promotion des intérêts nationaux dans la pêche, l'extension des industries existantes et la création d'industries nouvelles plus performantes. Le sous-secteur de la pêche industrielle et de ses industries annexes en sont les bénéficiaires exclusifs. L'objectif visé était d'accroître la puissance de pêche des unités industrielles et, par là, les débarquements et les exportations.

Des fonds spéciaux (bonification d'intérêt, garantie, participation) étaient prévus pour rendre le crédit maritime plus souple et ses prestations moins onéreuses que celles des banques commerciales.

Parallèlement, jusqu'à une date récente (1987), seule la SONAGA [1] à travers les projets "maîtrisards" exerçait un financement marginal de la pêche artisanale. L'ouverture étroite des opérateurs économiques du sous-secteur artisanal sur les marchés financiers formels résultait de la combinaison de plusieurs facteurs : revenus saisonniers, difficultés des banques à immobiliser l'épargne dégagé, insuffisance d'actifs pouvant servir de garanties aux prêts et non affiliation à une compagnie d'assurances pour couvrir les risques de non-paiement.

### *2.3 Code des investissements*

Des mesures d'allégement fiscal dans le cadre du code des investissements (Loi 87-24 du 18 août 1987) permet aux professionnels de la pêche de bénéficier d'une exonération assez substantielle des droits d'entrée des navires et des équipements de pêche. En plus de l'assouplissement de la législation sociale pour tenir compte du caractère saisonnier de leurs activités, les armateurs étrangers bénéficient aussi d'une liberté de transfert des capitaux et revenus générés. Les conditions d'agrément au code des investissements ont été nettement assouplies. En effet, l'armateur doit simplement disposer d'une licence de pêche, investir au moins 5 millions FCFA, financer son investissement sur fonds propres à hauteur d'au moins 20 à 30 % suivant la nature de son entreprise et créer un minimum de 3 emplois permanents sénégalais.

### *2.4 Financement du secteur de la pêche*

A travers les quatre premiers plans de développement économique et social (1961-1977), la volonté des autorités publiques de développer quasi-exclusivement la pêche industrielle est manifeste. Pendant cette période, les actions retenues pour ce sous-secteur mobilisent en moyenne plus de 80 % des dépenses prévues pour l'ensemble du secteur de la pêche avec un taux de record de 90 % lors du troisième plan (Dème, 1991) (tabl. 1).

La tendance vers un partage équilibré des moyens financiers affectés à la pêche observée à partir du Cinquième Plan entre les deux sous-secteurs artisanal et industriel est trompeuse et pour deux raisons essentielles. Premièrement, la pêche artisanale étant condamnée dans l'optique des pouvoirs publics à évoluer vers des formes industrielles plus performantes (Chauveau, 1988), plus d'un milliard de FCFA a été prélevé des prévisions de réalisations dans le secteur artisanal pour financer cette opération de modernisation de la pêche par l'acquisition de sardiniers et de cordiers entre 1960 et 1980.

1. Société Nationale de Garantie, d'Assistance et de Crédit.

Deuxièmement, le classement du Projet de Surveillance de la Pêche Sénégalaise, concernant quasi-exclusivement la pêche industrielle, dans la rubrique pêche artisanale absorbe près de la moitié des fonds destinés à ce sous-secteur.

Globalement on peut retenir que le niveau de financement de la pêche artisanale, en comparaison avec la pêche industrielle, est resté faible malgré la priorité exclusive accordée à ce sous-secteur dans le discours officiel.

Malgré ce soutien financier important, la pêche industrielle est restée déficitaire et les usines sont en grande partie approvisionnées par les artisans. Quelles sont les stratégies adoptées par les industriels ?

## 3. STRATÉGIES D'APPROVISIONNEMENT DES USINES

### *3.1 Relations pêcheurs-usiniers*

Dans le souci d'assurer la régularité de leurs approvisionnements en produits halieutiques, certaines usines font appel à des pêcheurs artisans et vont jusqu'à leur procurer tout l'équipement nécessaire à leur activité. Ces derniers pêchent et réservent exclusivement le produit de leur pêche à l'usine, qui l'achète aux prix convenus à l'avance. Le remboursement s'effectue par prélèvement systématique lors de la livraison des produits. En général, 50 à 100 FCFA sont prélevés par kilogramme de poisson livré. Il s'établit ainsi un contrat de quasi-intégration entre le pêcheur et l'usine (Dème, 1983 ; Dème et Diadhiou, 1990).

### *3.2 Relations mareyeurs-usiniers*

La situation financière déficitaire de la plus part des usines exportatrices de poisson ne leur permet pas d'armer leurs propres unités industrielles. A côté des pêcheurs, certaines sociétés font appel à des mareyeurs. Elles mettent à leur disposition des moyens financiers et des moyens de transport pour collecter les produits pêchés par les artisans le long du littoral. Ces mareyeurs reçoivent en contrepartie une commission qui est fonction du tonnage collecté.

Pour d'autres usines, les mareyeurs sont des agents salariés qui en plus de leurs salaires perçoivent des primes en fonction du tonnage livré.

Avec les détournements fréquents des moyens financiers et matériels mis à leur disposition ainsi que des produits collectés, certaines usines se limitent à proposer aux mareyeurs des prix suffisamment rémunérateurs pour s'assurer leur exclusivité.

## 4. PÊCHE ARTISANALE ET EXPORTATIONS : EFFETS PERVERS

La place de choix qu'occupe la pêche artisanale dans la politique d'autosuffisance lui fait bénéficier d'un soutien financier de l'Etat à travers des subventions et des détaxes. Ainsi les moteurs hors bord, les filets de pêche et les pièces de rechange sont vendus aux pêcheurs exemptés de droits de douane et de taxes et le carburant intègre une dépéréquation de près de 64 % de son prix total. Cependant l'orientation d'une partie de la production du sous-secteur artisanal vers les marchés extérieurs par le biais des usines qui bénéficient d'une subvention à l'exportation nous amène à poser la question de savoir qui bénéficie finalement de ces mesures financières et quels sont les résultats obtenus au regard des objectifs assignés à la pêche artisanale.

### *4.1 Exportations et marché local*

Les pêcheurs artisans fournissent un peu plus de 39 % des produits servant à la confection des farines (Lleres, 1986). Jusqu'en 1982, la SOPESINE [2], elle seule, transformait près de 20 000 tonnes de sardinelles et d'ethmaloses, fournies

2. Société des Pêches du Sine.

exclusivement par la pêche artisanale, en farine et huile de poisson destiné au marché mondial de l'alimentation du bétail. Est-il judicieux pour un pays où sévit une sous-alimentation protéique de favoriser le développement de telles industries d'autant plus que les espèces transformées sont prisées par les populations locales et que leurs valeurs marchandes sont en adéquation avec les revenus existant à l'intérieur du pays. Pire, la subvention par kilogramme de poisson débarqué à la SOPESINE estimé à 22 FCFA représentait trois fois le prix payé aux pêcheurs par l'usine. Ce qui renforce l'idée que ce sont les industries locales et le consommateur étranger qui profitent le plus de la politique d'aide à la pêche artisanale (Freon et Weber, 1985 ; Dème, 1989). Selon les dernières statistiques disponibles, la contribution du poisson dans la fourniture de protéines animales avoisine les 15 % dans les zones rurales éloignées de la côte. En conséquence, il faut réserver exclusivement aux populations locales les espèces à faible valeur commerciale sur le marché international et limiter strictement la production de farine de poisson pour l'alimentation animale aux déchets des usines et aux seules espèces impropres à la consommation humaine.

L'un des objectifs de l'aide publique au sous-secteur de la pêche artisanale est de fournir du poisson de bonne qualité à un prix abordable aux consommateurs sénégalais. Cependant la présence permanente des usines sur les plages a favorisé une hausse rapide du prix du poisson au débarquement. Ainsi les prix des espèces nobles ont plus que triplé ces dix dernières années.

### *4.2 Transfert d'effort et types de pêche*

Les usiniers ont fortement influencé les orientations de la pêche artisanale. Sous leur impulsion, de nouveaux types de pêche sont apparus et ne se sont développés que pour l'exportation. On peut citer la pêche des céphalopodes à la turlutte et au casier introduite par les industriels japonais, celle de la langouste au filet fixe développée par les Grands Viviers, la pêche de poissons nobles à la palangrotte ainsi que celle de la crevette à Ziguinchor initiée par les industriels de cette localité.

Parallèlement, les pêcheries jusqu'ici orientées vers l'autoconsommation ont également rapidement évolué. Ainsi de nouvelles stratégies d'exploitation des ressources sont apparues (Bakhayokho et Kebe, 1989). C'est ainsi qu'en période de pêche des espèces nobles à haute valeur marchande comme les céphalopodes et la sole, tous les types de pêche artisanaux se tournent vers l'exploitation de ces espèces. On assiste ainsi à des reports importants d'effort des espèces devant approvisionner le marché local vers celles destinées à l'exportation. Par exemple, de juin à septembre sur le Petite Côte presque toutes les pêcheries artisanales recherchent les seiches et les poulpes. Il a même été constaté que des pêcheries de pélagiques à la senne tournante et au filet maillant encerclant se convertissent en pêcheries de démersaux à la turlutte pour capturer des poulpes. De même, d'octobre à mai, beaucoup de pirogues qui opéraient à la ligne utilisent le filet à soles.

Globalement le poisson destiné au marché local devient de moins en moins disponible au fur et à mesure que la pression de pêche est orientée vers les espèces exportables.

### *4.3 Autres effets pervers*

Pour la pêche industrielle, l'exploitation de la ressource est assujettie à l'obtention d'une licence de pêche et au paiement de compensations financières pour les armateurs étrangers. Une stratégie récente adoptée par ces derniers consiste à intégrer les deux types de pêche. Les pirogues artisanales remorquées jusqu'aux lieux de pêche par un bateau-mère sont chargées de capturer le poisson et de le vendre au bateau qui leur assure en plus un soutien logistique. Le recours des industriels aux unités artisanales leur permet d'améliorer leur approvisionnement tout en contournant les modalités d'accès à la ressource, ce qui constitue un manque à gagner énorme pour l'Etat.

Ces pratiques permettent aux bateaux industriels d'accéder aux ressources disponibles dans la frange côtière réservée exclusivement à la pêche artisanale.

Concernant les cargos non basés à Dakar, en général, les pêcheurs artisans se font avoir en fin de campagne car leurs employeurs "oublient" souvent de venir régler les comptes.

## 5. CONCLUSION GÉNÉRALE

Notre analyse remet en cause la théorie dualiste consistant à opposer au secteur dit "traditionnel" un secteur dit "moderne". Ces deux secteurs sont intimement liés, certaines usines fonctionnent totalement ou en grande partie grâce aux apports de la pêche artisanale et, réciproquement, certains types de pêche artisanale ne se sont développés que pour l'exportation.

L'impact de la pêche artisanale dans l'autosuffisance alimentaire du pays a poussé les pouvoirs publics à lui octroyer des subventions, des transferts et des détaxes ; seulement l'orientation de ce secteur vers les marchés extérieurs fait que ce sont plutôt les industriels de la place et le consommateur étranger qui en sont les bénéficiaires.

Source d'emplois et de devises, grand producteur de protéines animales pour une population en croissance rapide, maillon essentiel dans l'approvisionnement des usines et des marchés, la pêche artisanale doit désormais bénéficier d'une distribution plus équilibrée des capitaux disponibles pour le développement du secteur.

Face aux besoins importants des populations locales en protéines animales et la faible couverture en milieu rural, la production de farine de poisson doit être strictement limitée aux déchets des usines et aux espèces impropres à la consommation humaine. Cette mesure doit être accompagnée par une meilleure valorisation de la production artisanale sur le marché local. En effet l'essentiel de l'aide à la pêche artisanale a été concentrée sur la production, en marginalisant les aspects commerciaux. Un transfert d'une partie de ces subventions de la production vers la commercialisation permettrait une meilleure distribution du poisson à l'intérieur du pays.

# Stratégies technologiques dans les industries de transformation

**Leïla Temri**

Agropolis Stratégies, Centre International des Hautes Etudes Agronomiques Méditerranéennes,
Institut Agronomique Méditerranéen de Montpellier,
3191, route de Mende, B.P. 5056, 34033 Montpellier, France

ABSTRACT

*Since the whole industry is affected by technological changes and restructuring movements, production rationalization and automation seem to become the main requirements for competitiveness. The main purpose of this paper is to set out conditions and stakes for technological changes in the seafood processing industry in respect to specificities of the sector. What are the main advantages of automation in relation to the constraints threatening the firm's production systems ? What are the obstacles to automation in relation to the supply features (espacially quantitative and qualitative uncertainty) ? Perspectives of improvement for the seafood industry production systems will be compared to theoritical developements concerning technological changes, strategy and production rationalization, by the mean of an inquiry realised in France.*

RÉSUMÉ

*Dans le cadre du mouvement de changement technique et de restructuration qui affecte l'ensemble des industries, la rationalisation de la production voire son automatisation semblent devenir des impératifs majeurs de compétitivité. L'objectif de cette communication est de présenter les conditions et enjeux de ce changement technique dans les industries de transformation des produits de la mer, compte tenu des spécificités de ce secteur. Quels sont les avantages perçus de l'automatisation par rapport aux contraintes actuelles qui pèsent sur les systèmes de production ? Quels sont les obstacles à l'automatisation, en particulier en regard des caractéristiques de l'approvisionnement (incertitude quantitative et qualitative) ? Une enquête réalisée en France auprès d'entreprises permet de positionner la problématique de l'amélioration des systèmes de production dans le secteur concerné par rapport aux approches théoriques.*

## 1. INTRODUCTION

L'accélération des mutations technologiques constitue l'une des évolutions caractéristiques de l'environnement actuel des entreprises. Celles-ci doivent l'intégrer à tous les niveaux, et en premier lieu dans la définition de leurs stratégies. Ces mutations peuvent affecter toutes les composantes de l'entreprise, mais touchent particulièrement leurs systèmes de production, c'est-à-dire, en simplifiant, leurs systèmes de transformation des inputs, les matières premières, en outputs, les produits finis. Dans ces conditions et dans une situation de concurrence accrue, la rationalisation de la production devient un impératif majeur de compétitivité. Parmi les différentes alternatives d'amélioration des systèmes de production, l'automatisation est considérée par certains auteurs comme une évolution inéluctable, voire incontournable. Notre objectif est de présenter les enjeux et les conditions de ce changement technique, dans les industries de transformation des produits de la mer.

En effet, les industries agro-alimentaires dans leur ensemble présentent un certain nombre de caractéristiques qui les différencient des autres types d'industries. Le secteur de la transformation des produits de la mer est en outre particulièrement marqué par ses relations avec l'amont, c'est-à-dire la pêche, et les incertitudes qui en découlent. Nous étudierons donc les implications de ces spécificités dans le cadre de l'amélioration des systèmes de production des entreprises de notre secteur.

Dans une première partie, nous présenterons les approches théoriques sur lesquelles s'appuie notre travail. Dans une deuxième partie, nous analyserons les spécificités des industries agro-alimentaires en général, puis du secteur de la transformation des produits de la mer, en regard des perspectives d'amélioration de leur système de production. Puis nous présenterons les résultats d'une enquête menée auprès d'entreprises de transformation, afin d'identifier leurs besoins et intentions en matière de production. Ces résultats nous permettront de positionner le secteur de la transformation par rapport aux approches théoriques et de cerner la problématique de l'amélioration des systèmes de production dans le secteur considéré.

## 2. LE CHANGEMENT TECHNIQUE, SES IMPLICATIONS STRATEGIQUES, ET LE RENOUVEAU DE LA PRODUCTION

Toute entreprise vise à améliorer sa compétitivité, c'est-à-dire son *"aptitude à soutenir durablement la concurrence"* (Marchesnay *et al.*, 1984). A cet effet, elle définit une stratégie qui doit lui permettre de *"répondre avec le maximum d'efficacité aux impulsions de son environnement"*. Cet environnement est aujourd'hui marqué par un certain nombre de mutations, et en particulier par l'évolution technologique. Celle-ci rend nécessaire l'intégration du facteur "technologie" en tant que facteur compétitif dans la stratégie de l'entreprise. D'autre part, elle touche particulièrement la fonction "production", qui retrouve ainsi une place centrale dans les préoccupations des entreprises, et peut s'avérer une arme compétitive efficace.

L'automatisation des systèmes de production, considérée, dans notre cas, comme une innovation destinée à régénérer des "technologies déjà établies" dans un secteur ancien (Larue de Tournemine, 1991), constitue l'une des possibilités ouvertes aux entreprises par ces mutations technologiques. L'ensemble des techniques et procédures concernant l'automatisation des systèmes de production, élargie à leur gestion, constitue une démarche appelée "productique".

Dans un premier temps, nous tenterons de préciser, à partir des développements analytiques récents concernant le changement technique et l'innovation, les contraintes imposées aux entreprises par les mutations technologiques.

Dans un deuxième temps, nous expliciterons les implications de ces changements pour l'analyse stratégique.

En troisième lieu, nous présenterons les travaux consacrés au renouveau de la fonction "production" et à son intégration en tant que variable stratégique.

Enfin, nous ferons le point sur le débat concernant la productique dans les industries agro-alimentaires.

### *2.1 Contraintes induites par le processus de changement technique et l'innovation*

Longtemps ignorée par les économistes, et considérée comme une variable exogène, la technologie a été intégrée dans le champ de l'économie par Marx puis Schumpeter, qui a mis en évidence le rôle de l'entrepreneur innovateur (Parent, 1978).

D'inspiration néo-schumpeterienne, l'école évolutionniste, développée notamment par Nelson, Winter, Rosenberg, Freeman, Dosi, propose une conception du changement technique et de l'innovation comme étant un processus de développement d'un contenu technologique potentiel donné, exogène, suivant une voie dessinée graduellement par interaction entre des variables technologiques et économiques.

Amendola et Gaffard (1988) soulignent le caractère séquentiel et surtout la spécificité de ce processus : il sera orienté *" de manière à servir les intérêts particuliers, et à résoudre les problèmes spécifiques de ceux qui* [le] *conduisent..."*. Ce sont donc eux qui s'approprieront les résultats obtenus.

Larue de Tournemine (1991) note que cette analyse rend impérative pour les entreprises leur participation au processus afin de *"bénéficier de la dynamique cumulative du développement des technologies, c'est-à-dire des phénomènes d'apprentissages, de l'amélioration des savoirs scientifiques et des capacités managériales et organisationnelles "*.

Foray et Zuscovitch (1988) rappellent le caractère irréversible du processus d'innovation : lorsqu'un choix technologique est effectué, ceci se fait au détriment des autres technologies disponibles, et les applications de la technologie choisie auront elles-mêmes toutes les chances d'être développées ultérieurement. Selon Fanfani *et al.* (1990), cette irréversibilité signifierait que la consolidation d'un choix ou "paradigme" technologique tendrait à éliminer les précédents, et la base de la compétitivité deviendrait alors la capacité à maîtriser le nouveau paradigme. Ces auteurs remarquent toutefois que dans le domaine agro-alimentaire, coexistent simultanément plusieurs paradigmes d'apparition non synchrone.

Si l'on adopte cette approche du changement technique et de l'innovation, il semble donc important pour l'entreprise de participer au processus, afin de le façonner à son profit, de bénéficier des effets de l'accumulation par l'expérience et l'usage, et de s'intégrer dans les nouvelles normes techniques.

### *2.2 Les implications stratégiques de l'évolution technologique*

Il importe de prendre en compte l'évolution technologique dans l'analyse stratégique. En effet, elle a modifié les règles du jeu concurrentiel, et ceci à plusieurs niveaux.

- Tout d'abord, la technologie possède, selon Porter (1986) un caractère déterminant de la structure des secteurs. Son évolution induit donc des modifications de cette structure :

  • A l'intérieur d'un secteur, les activités peuvent être redéfinies, élargies, ou au contraire rétrécies. Leur développement peut être accéléré, ou, à l'inverse, freiné (Dussauge, Ramanantsoa, 1987).

  • Il en découle une modification du champ concurrentiel, et également de la structure de la concurrence : certains concurrents peuvent être éliminés, d'autres, éventuellement issus de secteurs antérieurement distincts, vont apparaître.

  • Enfin, l'évolution technologique peut induire une réorganisation industrielle, dans le secteur, mais aussi des relations avec d'autres opérateurs, notamment les fournisseurs d'équipements (Perez, 1987).

- En règle générale, l'évolution technologique rend nécessaire, mais aussi permet, une orientation des objectifs stratégiques, vers la recherche de flexibilité, de différenciation et de renouvellement des produits, adaptée aux évolutions de la demande (Larue de Tournemine, 1991). De plus, pour une activité donnée, les facteurs clés de succès, c'est-à-dire les facteurs dont la maîtrise est nécessaire pour assurer la compétitivité de l'entreprise dans un secteur, peuvent varier. Certaines entreprises seront mieux armées que d'autres pour répondre aux nouvelles exigences. La diffusion de l'innovation technologique est ainsi source de performances inégales pour les entreprises (Quelin, 1988).

- Enfin Porter (1986) développe le rôle de la technologie en tant que source d'avantage concurrentiel pour la firme dans le cadre des deux principales stratégies génériques qu'il a identifiées : stratégie de domination par les coûts, et stratégie de différenciation.

Dans tous les cas, il apparaît indispensable de prendre en compte la technologie aux deux niveaux de la stratégie : lors de l'analyse, du diagnostic stratégique, tant externe qu'interne, et dans la définition de la stratégie globale de l'entreprise.

### *2.3 Le renouveau de la fonction production*

Sous l'influence conjuguée de l'évolution technologique et des nouvelles exigences du marché, l'entreprise doit adapter sa fonction production. En même temps, celle-ci devient une arme compétitive, à condition de s'insérer de manière cohérente dans la stratégie globale de l'entreprise, et de ne plus être subordonnée aux fonctions marketing et finance.

- Le premier, Skinner (1969) a montré qu'il existait une relation entre stratégie et décisions de production, et a préconisé l'intégration des objectifs de production dans la stratégie globale de l'entreprise. De nombreux auteurs l'ont suivi dans cette voie. Lenoir (1986) remarque toutefois que les nouvelles technologies de production peuvent avoir elles-mêmes des implications stratégiques, en permettant de nouvelles orientations et stratégies. Ainsi, la relation entre stratégie et production est interactive et non univoque.

- La conjugaison de l'évolution technologique et des mutations des besoins du marché a plusieurs conséquences sur la fonction production. Tout d'abord, une modification des objectifs de la fonction, avec un fait nouveau : la recherche de flexibilité. La productivité reste cependant un objectif pertinent, favorisé également par l'évolution technologique, qui permet de lui donner un contenu plus global. Mieux encore, les développements récents des technologies de production dites "flexibles" permettent de dépasser le traditionnel dilemme productivité-flexibilité, et de concilier des objectifs autrefois conflictuels. En deuxième lieu, on constate une imbrication de plus en plus étroite entre politique de produit et politique de production, mais également de la production avec les autres fonctions de l'entreprise, créant des effets de synergie. Enfin, selon Ait el Hadj (1989), l'intégration des technologies de l'information dans les systèmes de production a entraîné des modifications allant au-delà du seul domaine technologique, mais touchant l'organisation et la gestion.

### *2.4 La productique*

Les développements consacrés à la productique synthétisent l'ensemble des approches théoriques énoncées ci-dessus, tout au moins ceux concernant l'interaction technologie-stratégie, et la fonction production.

Ainsi, Collombel et Joignaux (1987) constatent que l'évolution des systèmes de production est caractérisée par trois phénomènes : la recherche de flexibilité, pour répondre à la variabilité croissante de la demande ; l'irréversibilité des choix d'investissements, compte tenu du coût qu'ils représentent et des mutations organisationnelles qu'ils induisent. Cette irréversibilité confère un caractère stratégique à ces choix ; enfin, la complexification des systèmes de production, qui entraîne la recherche de procédures de simplification et d'intégration des processus. Ces évolution impliquent, au niveau des systèmes de gestion, la mise en place de nouveaux modes d'organisation et de régulation, ainsi que la mise au point de nouveaux critères d'évaluation des coûts et des résultats. Enfin, la démarche productique entraîne une redéfinition des relations externes, en particulier avec les clients et les fournisseurs, particulièrement ceux de biens d'équipement. Elle peut même induire des modifications dans l'organisation d'une filière.

Ces travaux confirment l'existence de relations dynamiques entre évolution technologique, stratégie et systèmes de production, et par là la nécessité d'une évolution des systèmes de production. Ils mettent en lumière le rôle de l'évolution de la demande dans cette dynamique. Mais, en réaffirmant le caractère irréversible et stratégique de l'investissement productique, l'importance des risques qu'il comporte, les modifications des relations externes de l'entreprise et même les reconfigurations sectorielles auxquelles il peut conduire, ils montrent la nécessité de s'interroger sur la pertinence d'une alternative à l'investissement productique : une rationalisation plus organisationnelle que technique de la production.

Qu'en est-il dans les industries agro-alimentaires, et plus précisément dans le secteur de la transformation des produits de la mer ?

## 3. LES PERSPECTIVES D'AMELIORATION DES SYSTEMES DE PRODUCTION DANS LES INDUSTRIES DE TRANSFORMATION DES PRODUITS DE LA MER

Comme l'ensemble des industries, les industries agro-alimentaires doivent s'adapter aux évolutions du système technique, et intégrer les mutations en cours. Nous préciserons leurs caractéristiques propres puis présenterons les travaux de recherche concernant les améliorations de leurs systèmes de production.

Le secteur de la transformation des produits de la mer se distingue en outre par ses relations particulières avec l'aval, la pêche. Une enquête nous a permis de préciser les implications de cette spécificité, en particulier par rapport au rôle éventuel de l'automatisation, et les besoins en amélioration des systèmes de production.

*3.1 Industries agro-alimentaires et évolution des systèmes de production*

Un certain nombre de recherches ont été consacrés à l'évolution des industries agro-alimentaires face aux mutations technologiques (notamment INRA-ESR/ENSAM, 1991). Ils précisent les principales caractéristiques du secteur et les problèmes spécifiques posés dans le cadre de l'amélioration des systèmes de production, et en particulier de l'automatisation. Les industries de la viande ont fait plus particulièrement l'objet d'études sur ce thème.

### 3.1.1 Des marchés spécifiques, marqués par l'évolution de la demande

Il s'agit en effet des traiter des produits vivants, périssables, présentant une hétérogénéité qualitative des variations de prix considérables, et souvent une incertitude quantitative (Joignaux, 1988). La demande est caractérisée par une exigence croissante de variété des produits et de qualité. D'un point de vue technologique, cette dimension s'étend progressivement d'une acception purement sanitaire à l'adaptation à des besoins dérivés de l'outil industriel et aux attentes du consommateur final (Fanfani *et al.*, 1990). Selon R. Perez (1989), les marchés sont diversifiés, allant du local au mondial, mais globalement ils sont marqués par le ralentissement à long terme de la demande, une certaine saturation, et les pressions croissantes de la grande distribution. Enfin, l'internationalisation de ces marchés entraîne une augmentation de la concurrence, et un renforcement du poids des normes internationales, et par là de la règlementation. Celle-ci soutient fortement les exigences de qualité sanitaire du consommateur, et agit sur les échanges, particulièrement par des interventions sur l'évolution des prix.

### 3.1.2 Concentration des structures de production

Les structures de production présentent une grande hétérogénéité de taille et de procédés de transformation. Mais on observe une tendance aux reconfigurations organisationnelles et financières, avec une concentration plus importante, et, selon Schwind (1987), une diminution du nombre d'unités de production.

### 3.1.3 La difficile modernisation des outils de production

Plusieurs secteurs, en commençant par les industries de process (huile, lait par exemple), ont déjà amorcé la modernisation significative de leur outil de production. Le Bars et Molle (1986) énoncent les caractéristiques de l'évolution des processus de production dans les industries agro-alimentaires, dans une perspective d'automatisation : recherche de flexibilité à cadence rapide -remplissage, conditionnement-, discontinuités exigeant des manipulations coûteuses -tri, conditionnement-, et enfin abondance de la quantité d'information à recueillir et à traiter pour assurer le contrôle des processus. Pour ces auteurs, les problèmes essentiels actuels de l'automatisation sont l'inexistence de capteurs d'information adéquats, et les difficultés de traitement de l'information disponible, émise à un débit considérable. Mais ces spécificités ouvrent des perspectives intéressantes à l'application des nouvelles techniques de traitement de l'information et à la robotique.

### 3.1.4 Un exemple : la productique dans les industries de la viande

Des travaux ont été consacrés plus particulièrement à la productique dans les industries de la viande (notamment Perez, Renault, 1989), qui présentent de nombreuses analogies avec celles des produits de la mer. Il apparaît tout d'abord que la nature des besoins en automatisation diffère selon le stade dans la filière de production. En particulier, le besoin de flexibilité est plus fort en aval qu'en amont. Par ailleurs, l'automatisation des industries de la viande se heurte à trois types de problèmes. D'une part, il existe des "verrous technologiques" à l'automatisation, dus à l'origine vivante de la matière première et à la discontinuité des processus. Les orientations qui seront induites par la résolution de ces problèmes n'apparaissent pas encore nettement. En second lieu, interviennent des facteurs économiques et financiers. L'investissement productique est à haut risque, comme pour toutes les innovations ; d'autres investissements, notamment sanitaires, sont prioritaires, du fait de la règlementation publique ; enfin, le marché étant globalement en stagnation, voire en régression, la rentabilité du secteur est faible, et laisse peu de ressources d'autofinancement. Ainsi, la recherche de flexibilité de l'outil de production peut entraîner des rigidités de nature financière et relationnelle telles que la dépendance vis-à-vis des fournisseurs en équipements. En troisième lieu, l'automatisation du secteur est freinée

par des facteurs humains. Beaucoup d'entreprises sont des PME familiales, où les connaissances scientifiques et technologiques sont souvent faibles, et les mentalités peu imprégnées de logique industrielle. Tous ces facteurs expliquent que le secteur des industries de la viande présente un certain retard dans l'évolution de son outil de production par rapport à d'autres industries agro-alimentaires.

*3.2 Amélioration des systèmes de production dans le secteur de la transformation des produits de la mer*

### 3.2.1 Caractéristiques du secteur

Les caractéristiques des industries agro-alimentaires s'appliquent globalement au secteur de la transformation des produits de la mer, notamment en ce qui concerne l'évolution de la demande -variété et qualité-, et les rôles respectifs de la règlementation publique et de l'environnement international. Les relations avec l'amont, la pêche, sont en revanche marquées par une incertitude plus importante, qualitative comme quantitative, due à la non maîtrise du renouvellement de la ressource. Le secteur se trouve en outre au centre de deux types de contraintes : en amont, des disponibilités en stagnation, voire en régression, et en aval une demande soutenue, en évolution permanente. Il en résulte une augmentation considérable des prix au niveau mondial, et un développement important des échanges. Parmi les produits alimentaires et forestiers, c'est le secteur dont les échanges mondiaux ont connu la plus forte augmentation ces dernières années (FAO, 1989). En France les produits de la mer participent structurellement et durablement au déficit du commerce extérieur, tant pour les produits frais que pour les produits transformés. Les perspectives d'augmentation des apports de poissons frais semblent fortement compromises par les mesures communautaires visant à limiter les captures. En revanche, des possibilités de meilleure maîtrise de la valorisation existent, soutenues par les tendances de la consommation, qui se déplace des produits frais vers les produits élaborés.

Le secteur est segmenté en plusieurs sous-ensembles correspondant généralement à des technologies différentes : frais, conserves, produits séchés, salés, fumés, surgelés. Cette segmentation traditionnelle est de plus en plus obsolète. En effet, d'une part l'évolution technologique, conduit à l'apparition fréquente de nouvelles technologies, telles que la fabrication du surimi par exemple. D'autre part, on observe dans la presse spécialisée une segmentation de type plus "marketing", basée sur l'utilisation du produit : plat principal, entrée, etc... quelle que soit la technologie employée. En troisième lieu, une même technologie permet la fabrication de produits ayant des degrés d'élaboration divers. Cette évolution a pour conséquence la difficulté d'identification des marchés, et de positionnement des entreprises. Quelle que soit la segmentation retenue, les marchés n'évoluent pas de la façon identique. Certains segments déclinent, d'autres émergent. Cette évolution inégale est certes à relier aux transformations de la demande, mais également, sans doute dans une moindre mesure, au dynamisme propre des opérateurs dans les segments considérés.

Les préoccupations majeures en matière de technologie, telles qu'elles ressortent du dépouillement de la presse spécialisée, d'entretiens avec les professionnels, administratifs et chercheurs du secteur, se situent surtout autour de la recherche de nouveaux procédés de conservation -sous-vide, ionisation, etc...-, l'élaboration de nouveaux produits, et la valorisation de nouvelles espèces marines. L'intérêt pour l'amélioration des systèmes de production, en particulier pour l'automatisation, semble plutôt le fait de grandes entreprises privées, ce qui limite considérablement la diffusion des informations.

Concernant les processus de production, on notera qu'ils sont très fragmentés, séquentiels, avec des opérations très spécialisées. D'ailleurs, les fabricants proposent essentiellement des machines spécialisées, et ce sont d'autres intervenants, issus généralement de secteurs agro-alimentaires différents, qui mettent au point des lignes complètes, intégrées, adaptées aux besoins propres de chaque entreprise cliente, en reliant et combinant des machines d'un ou plusieurs constructeurs. Certaines rares entreprises mettent elles-mêmes au point leurs équipements.

### 3.2.2 Perspectives d'amélioration des systèmes de production : les résultats de l'enquête

Afin de mieux évaluer les perspectives d'amélioration des systèmes de production dans les entreprises de transformation des produits de la mer, nous avons réalisé une enquête auprès d'un échantillon de 24 entreprises, réparties dans toute la France, et opérant dans plusieurs secteurs de la transformation, en dehors du mareyage que nous avons considéré comme une activité purement commerciale. L'objectif de cette enquête était double : d'une part identifier les besoins en matière

d'amélioration des systèmes de production, d'autre part évaluer l'impact des incertitudes liées aux approvisionnements sur la fabrication et la gestion de la production. Nous nous situons au niveau de la définition globale des objectifs de production, en liaison avec la stratégie de l'entreprise. Nous présentons ici une première approche des résultats, un traitement plus approfondi devant être effectué par la suite. Il convient enfin de préciser que cette enquête revêt un caractère exploratoire, qualitatif, et ne prétend donc pas à une représentativité statistique. Elle constitue néanmoins un point de départ indispensable, car à notre connaissance, aucune publication sur ce thème, dans le secteur de la transformation des produits de la mer, n'est disponible.

• Etat actuel du système de production et perspectives

Pour apprécier l'état d'automatisation du système de production, nous avons proposé une échelle de 5 niveaux, fortement inspirée du travail de Kalika (1988), en demandant d'estimer le pourcentage de l'activité correspondant à chacun d'entre eux.

- A travers l'échantillon, le secteur apparaît peu automatisé : seules 8 entreprises sur 24 estiment leur niveau d'automatisation supérieur à 10 %. Seules 2 entreprises font état de la possession d'au moins une machine entièrement automatisée, et aucune d'un système complet intégré. Par contre, 5 entreprises déclarent effectuer le travail entièrement à la main. A titre indicatif, nous obtenons un taux moyen d'automatisation -moyenne des taux d'automatisation- de 14 %, un taux moyen de travail manuel de 65,5 %, et un taux moyen de mécanisation de 20,5 %. Précisons que nous ne nous sommes préoccupés que de la fabrication, et n'avons délibérément pas cherché à évaluer l'informatisation périphérique, comme celle de la comptabilité ou de la gestion.

- Parmi les entreprises ayant un taux d'automatisation inférieur à 30 %, les principaux freins évoqués sont les suivants : en premier lieu, l'inexistence de machines adéquates. En second lieu, le coût trop élevé des équipements disponibles. Puis est mentionnée l'insuffisance du volume de production, qui ne justifie pas l'investissement, ensuite, l'inadéquation du matériel existant. Au total, les raisons plutôt techniques - inexistence ou inadéquation du matériel, qualité des produits- sont évoquées avec pratiquement la même fréquence que les raisons d'ordre managérial -coût, rentabilité, insuffisance du volume de production- (respectivement 14 mentions contre 13).

- Les entreprises mécanisées ou automatisées (14 sur 24) expliquent leurs choix avant tout par la recherche d'augmentation de la productivité : diminution des coûts de main d'oeuvre, augmentation de la productivité globale et du volume de production. Le souci de qualité des produits vient ensuite, puis l'amélioration des délais de fabrication et l'adaptation aux variations de volume de la demande, qui expriment le besoin de flexibilité.

- Sur l'ensemble de l'échantillon, plus de la moitié des entreprises souhaitent évoluer vers une automatisation plus grande de leurs équipements, de manière progressive. Un tiers envisage une simple réorganisation de leur système de production, sans investissement lourd (tableau 1). Ces intentions sont à relier d'une part aux préoccupations générales des entreprises quant à leur avenir, d'autre part aux besoins exprimés en matière d'amélioration des systèmes de production.

- Pour leur avenir, les entreprises craignent avant tout la concurrence, nationale ou internationale. En deuxième lieu, elles redoutent les conditions imposées par leur clientèle, en particulier quand celle-ci appartient à la grande distribution. Contrairement à notre attente, les inquiétudes quant aux approvisionnements n'arrivent qu'en troisième position, précédant l'incertitude quant à l'évolution de la demande. L'existence de débouchés ne semble préoccuper que modérément les entreprises (3 citations).

- En ce qui concerne l'amélioration des systèmes de production, les besoins en amélioration de la productivité sont largement supérieurs à ceux d'augmentation de la flexibilité ou de la qualité (tableau 2). Ce sont avant tout les coûts de main d'oeuvre et la productivité de la main d'oeuvre qui préoccupent les responsables de production. La progression de la productivité des machines n'est pas le souhait le plus fréquent, mais est le plus fréquemment cité comme besoin prioritaire. Les besoins en flexibilité sont exprimés surtout en termes de raccourcissement des délais de fabrication, et de polyvalence des équipements. Signalons enfin que plusieurs entreprises ont cité spontanément la mise aux normes européennes comme préoccupation importante, voire majeure.

Il semble donc globalement que pour faire face à l'intensification de la concurrence, les entreprises souhaitent moderniser leurs équipements dans le sens d'une automatisation plus grande, qui leur permettrait d'augmenter leur productivité, en limitant les coûts de main d'oeuvre. La polyvalence des équipements est en réalité souhaitée par un grand nombre d'entreprises, mais considérée comme une utopie à l'heure actuelle. Enfin, les entreprises, peu préoccupées par

l'incertitude quant à l'évolution de la demande, ne s'intéressent que modérément aux perspectives de flexibilité par rapport à cette demande. L'impératif de qualité leur paraît plus important, bien que certaines s'inquiètent de la difficulté de valorisation de la qualité par le marché.

• L'incertitude liée aux approvisionnements et ses conséquences sur la production

- Bien que la maîtrise des approvisionnements ne soit pas la préoccupation majeure des responsables de production, contrairement à nos attentes, ils y accordent quand même quelque importance, car elle entraîne certaines contraintes. L'inconvénient le plus vivement ressenti est l'instabilité des prix des matières premières. Vient ensuite le problème de la saisonnalité des apports, alors que la disponibilité des produits en saison n'apparaît qu'en dernière position. Les variations qualitatives, sanitaire d'abord, puis morphologiques, arrivent respectivement en troisième et quatrième position.

- Les principaux problèmes générés par ces incertitudes sont en premier lieu l'importance ou le coût des stocks de matière première, puis la difficulté de maîtriser les coûts de production. Les autres items proposés : difficulté d'honorer, qualitativement ou quantitativement, les commandes, respect des délais de production, et importance des stocks finis sont considérés comme un handicap moindre par les responsables de production.

Ces résultats confirment que l'impact de l'incertitude amont est ressenti par rapport aux coûts de production et non par rapport à la demande. Le concept de compétitivité par la flexibilité ne touche pas encore le secteur. Ce phénomène peut être expliqué par l'optimisme relatif, dans le secteur, quant à la tenue de la demande, généralement stable ou en croissance selon les segments. En revanche, l'amélioration de la productivité à travers les coûts de production est considérée comme la clé de la compétitivité face à l'accroissement de la concurrence.

## 4. CONCLUSION

En comparant les approches théoriques récentes en matière d'amélioration des systèmes de production aux réalités du secteur de la transformation des produits de la mer en France, on observe un décalage important :

- d'ordre technologique tout d'abord. L'automatisation ne touche que peu le secteur, et ne semble pas la préoccupation majeure, ni des entreprises, ni des institutions qui les entourent, ni même des constructeurs d'équipements. Ceux-ci se heurtent à des verrous technologiques forts, liés tout particulièrement à la nature des matières premières utilisées. L'atout essentiel -et souhaité- que constituerait la polyvalence des machines, par rapport aux opérations, mais surtout à la nature des entrants, n'est pas encore surmonté.

- d'ordre humain ensuite. La prise en compte de la flexibilité par rapport à la demande, et de l'atout que pourrait jouer l'outil de production dans cette optique, ne semble pas intégrée par les entreprises. On reste dans l'étape antérieure d'amélioration de la compétitivité par la maîtrise des coûts de production en augmentant la productivité, et en limitant les coûts de main d'oeuvre. C'est dans cette optique que l'automatisation apparaît comme un avantage, tandis que les obstacles majeurs sont perçus comme étant d'ordre technique ou financier. Il est à noter que paradoxalement, le risque lié au coût de l'investissement automatisé a souvent été relié à l'incertitude quant à l'évolution des débouchés, même si cela n'apparaît pas clairement dans les résultats.

Finalement, la demande de flexibilité semble orientée plus par rapport à l'amont qu'à l'aval, mais les caractéristiques de la pêche imposent des contraintes technologiques qui en limitent les possibilités. L'incertitude aval, quant à elle, est ressentie comme un risque qui restreint l'investissement automatisé, en contradiction avec les développements théoriques récents. On se trouve ainsi dans une logique particulière, qui exige des réponses adaptées. Les théories de l'évolution technologique et de ses conséquences sur la stratégie et la fonction production négligent en effet les contraintes liées à l'amont.

# Consumption of Seafood, Poultry and Meat in Restaurants vs. Supermarkets

**Toyokazu Naito, Richard S. Johnston and Ann L. Shriver ***

Department of Agricultural and Resource Economics, Oregon State University, Ballard Extension Hall 213, Corvallis, Oregon 97331-3601, USA

ABSTRACT

*There is considerable evidence to support the hypothesis that seafood, poultry and meat are close substitutes in consumer demand. Thus the relationships among prices are important in determining consumption patterns among these protein sources. In addition, there are at least two kinds of outlets in which seafood, poultry and meat are sold to consumers : retail stores, including supermarkets, and away-from-home outlets, including restaurants. Because restaurants and retail stores add different sets of services to their products (dining facilities vs. packaging, for example), one would expect the price relationships among the three protein categories to be different, as between the two outlets. In turn, this should lead to consumption patterns that are different in restaurants than in retail stores. Some, however, argue that this is not the case because the different prices in the two outlets can be assigned directly to the services provided by the respective outlets and thus should not be included in the prices of the protein items themselves. Under this argument, there should be no differences in the consumption patterns as between the two outlets. This paper presents a theoretical model of the issue, reviews the competing hypotheses, and discusses preliminary results of an empirical test.*

## 1. INTRODUCTION

The "shipping the good apples out" issue is a very interesting real economic phenomenon with several varied applications. The example cited in Borcherding and Silberberg (1978) gave the phenomenon its name : an irate consumer complained that in the state of Washington, where apples are grown, local markets carry only small, poor quality fruit. The consumer demanded to know why better quality apples were unavailable, and where they had gone. The answer was provided by a leading economist in the Seattle Times of October 28, 1975 :

* Acknowledgements : This paper reports on research supported, in part, by the OSU Sea Grant Program and by the Cooperative States Research Service, U.S. Department of Agriculture, under Agreement No. 92-34276-7140.

> "Suppose, for example, a "good" apple costs 10 cents and a "poor" apple 5 cents locally. Then, since the decision to eat one good apple costs the same as eating two poor apples, two good apples cost four poor apples. Suppose now that it costs 5 cents per apple (any apple) to ship apples East. Then, in the East, good apples will cost 15 cents each and poor ones 10 cents each. But now eating two good apples will cost three - not four poor apples. Though both prices are higher, good apples have become relatively cheaper, and a higher percentage of good apples will be consumed in the East than here."

This answer is supplied in the context of Alchian and Allen's proposition (1964) that if a given transport cost is added equally to the prices of two similar goods, then, because they will reduce the relative price of the more expensive (i.e., higher quality) good, the effect will be a relative increase in the consumption of the higher-quality good.

This proposition can be applied to other "fixed charge" phenomena. The application of interest to us is the impact of differing price ratios on consumer choices between seafood and comparable options. When a consumer purchases fish and other protein sources such as chicken or beef at a retail outlet, she faces a certain price comparison between these items. If we add an equal "fixed charge" to each of these items - such as the cost of restaurant preparation and presentation as a "center of the plate" menu item - this price comparison (ratio) will change. Do consumers perceive the difference between these price ratios, and act as theory would predict, consuming relatively more of the lower priced item at retail outlets and relatively more of the higher-cost protein at restaurants ?

The proposition is not without controversy. Its formulation has been debated in the literature, and we now have two different, alternative formulations. These two formulations differ in their assumptions about how consumers perceive prices. One formulation supports the hypothesis that consumers view the fixed per-unit charge as a change in the price ratio, as just discussed. The other formulation hypothesizes that consumers view the charge not as affecting the price ratio at all, but, rather, as a fixed lump-sum charge for a separate third good or service, or an "admission fee". In the restaurant, this would be the portion of the patron's bill which pays for everything other than the food cost of her meal, including decor, ambience, the services of waiters and maitre d's, heating, lighting, etc. Under this latter formulation, relative prices of the food items themselves would be the same for restaurants as for retail stores.

While the Alchian and Allen proposition has been applied to explain several economic phenomena, no statistical test has yet been devised for distinguishing between these two formulations. The purpose of our research is to empirically test the hypothesis of Alchian and Allen's proposition, and also to test the two alternative hypotheses concerning its formulation. To do so, we will examine whether the ratio of fish to meat consumption is different in restaurants than in retail food stores, in view of the different price ratios in the two markets.

While the present paper reports on some preliminary empirical results, its principal purpose is to review the central features of the model in some detail. Through this effort, we hope to convince the reader that any analysis of seafood consumption patterns that seeks to explain the relative growth of seafood sales in away-from-home outlets should be sensitive to the need to consider not only such factors as the rising opportunity cost of time (Prochaska and Schrimper) but also the central variable of economic choice : relative prices. For these purposes, we devote the bulk of the paper to the conceptual issues. Then drawing on the work of Opaluch (1982) we develop an econometric model that should permit us to explore competing hypotheses about choice behavior. To date, only preliminary testing of the competing hypotheses has been conducted. In this paper, we first summarize the theoretical basis of these models in part II. The model itself is presented in the next section (part III), with results of preliminary tests and conclusions presented in part IV.

## 2. THEORETICAL MODEL

### *2.1 The Original Alchian and Allen Proposition*

The original Alchian and Allen proposition was presented in a two-good world, involving a higher-quality good, $x_1$, with higher price $p_1$, and a lower-quality good, $x_2$, with lower price $p_2$. Their proposition can be graphically illustrated on a two-dimensional graph as in Figure 1.

Here the higher-quality good $x_1$ with price $p_1$ is depicted on the vertical axis and the lower-quality good $x_2$ with lower price $p_2$ is depicted on the horizontal axis. The individual consumer has income Y ; hence she faces a budget line AB,

where $p_1 > p_2$ is assumed so that the slope of AB is less than one in absolute value. In this situation, the utility-maximizing consumer purchases the bundle $(x_1^*, x_2^*)$ at point E, which is the point of tangency with the consumer's indifference curve $I_1$. The slope of line OG, $x_1^*/x_2^*$, gives the consumption ratio of $x_1$ to $x_2$. If a transportation or other "fixed" charge, $t$, is added equally to prices $p_1$ and $p_2$, the consumer having the same income and utility function will operate on the new budget line CD (which is steeper than AB). She will then choose a new bundle $(x_1^{**}, x_2^{**})$ at point F, tangent to indifference curve $I_2$. Hence, the slope of line OH, presenting the new consumption ratio between $x_1$ and $x_2$, is steeper than before ($x_1^{**}/x_2^{**} > x_1^*/x_2^*$). Therefore consumption of the higher-quality good $x_1$ (relative to the lower-quality good $x_2$) will increase as the "fixed" cost $t$ is added equally to both prices $p_1$ and $p_2$ ($p_1 > p_2$).

However, Alchian and Allen's proposition requires one important assumption : that no income effect exists (*i.e.* income changes are compensated). This assumption was suggested by Gould and Segal (1969). They showed that, if the lower-quality good is an inferior good and an income effect is permitted, then the proposition may no longer hold, indicating that the "no income effect" assumption is important in the application of Alchian and Allen's proposition. Moreover, in the real world, we have to consider more than the two goods of the Alchian and Allen formulation.

### *2.2 The Borcherding and Silberberg Formulation*

The theoretical model of the Alchian and Allen proposition is reformulated by Gould and Segal (1969) [1] and Borcherding and Silberberg (1978). Both models are algebraically demonstrated by use of the composite commodity theorem [2] and Hicks' law. They are very similar ; however the latter model is made more tractable by use of Hicks' third law [3].

Suppose we have a three-good world, where goods $x_1$, $x_2$, and $x_3$ have prices $p_1$, $p_2$, and $p_3$, respectively, and where $x_3$ is a composite commodity representing all other goods. Let $x_1$ and $x_2$ be, respectively, the higher-quality and lower-quality goods, so that $p_1 > p_2$. Assume $x_1$ and $x_2$ are transported from another location, with a unit transport cost $t$, and $x_3$ is produced locally, producing a set of prices $p_1 + t$, $p_2 + t$, and $p_3$.

In this situation, we can set up the dual (expenditure minimization) problem. From the solution to this problem, the income compensated demand functions are derived (Binger and Hoffman, 1988, pp. 183-193). Thus, we minimize the objective function given by :

$$M = (p_1 + t)\, x_1 + (p_2 + t)x_2 + p_3x_3, \tag{1}$$

subject to the constraint :

$$U(x_1, x_2, x_3) = U^0.$$

Solving this problem the generalized forms of these compensated demand functions for each of the three commodities will be :

$$\begin{aligned} x_1 &= x_1^U(p_1, p_2, p_3, t, U^0) \\ x_2 &= x_2^U(p_1, p_2, p_3, t, U^0) \\ x_3 &= x_3^U(p_1, p_2, p_3, t, U^0). \end{aligned} \tag{2}$$

These are demand functions which hold utility constant and allow income to vary. We consider only compensated demand here because income effects are always indeterminate.

1. Their formulation uses Samuelson's development of the theory of consumer behavior, as presented in *Foundations of Economic Analysis*, Cambridge, Mass. : Harvard Univ. Press (1948) : p. 90-124.
2. The composite commodity theorem states that if the prices for a group of $k$ (<n) commodities always change in the same proportion in n-commodity space, the aggregate demand for the $k$ commodities behaves as if they were a single commodity (Henderson and Quandt 1980, p. 48). This was first introduced by John R. Hicks, in *Value and Capital* , 2d. ed. London : Oxford Univ. Press (1939) : p. 312-313.
3. Hicks' third law is derived from the homogeneity of degree zero of the compensated demand curves, $x_i = x_i^U(p_1, ..., p_n, U^0)$, with respect to prices. From Euler's theorem, we have $p_1 \cdot \partial x_i^U/\partial p_1 + ... + p_n \cdot \partial x_i^U/\partial p_n \equiv 0$. Letting $s_{ij} = \partial x_i^U/\partial p_j$, the pure substitution effect on $x_i$ of a change in $p_j$, we have $p_1 s_{i1} + p_2 s_{i2} + ... + p_n s_{in} \equiv 0$. However, for compensated changes $s_{ij} = s_{ji}$ . Hence, $p_1 s_{1i} + p_2 s_{2i} + ... + p_n s_{ni} \equiv 0$. These results are known as Hicks' third law. The law can be stated succinctly as $\Sigma^n_{i=1} p_i s_{ij} = \Sigma^n_{j=1} p_j s_{ij} = 0$. Hicks' first two laws are, respectively, $s_{ij} = s_{ji}$, $s_{ii} < 0$. (Silberberg 1990 P342-343) .

According to Borcherding and Silberberg (1978), Alchian and Allen's proposition can be stated as :

$$\partial(x_1^U/x_2^U)/\partial t > 0. \tag{2}$$

That is, as the transport cost rises, consumption of the higher-quality good increases relative to that of the lower-quality good, holding utility and the prices of all other goods constant.

Further, expanding the quotient in equation (3) gives :

$$\partial(x_1^U/x_2^U)/\partial t = (x_2 \cdot \partial x_1/\partial t - x_1 \cdot \partial x_2/\partial t)(1 / x_2^2). \tag{3}$$

An increase in $t$ is equivalent to increasing $p_1$ and $p_2$ by the same amount, hence $\partial x_i/\partial t = \partial x_i/\partial p_1 + \partial x_i/\partial p_2$, i = 1,2 [4]. Letting $s_{ij} = \partial x_i/\partial p_j$, the Hicksian pure substitution terms, equation (4) becomes :

$$\partial(x_1^U/x_2^U)/\partial t = (x_1/x_2)(s_{11}/x_1 + s_{12}/x_1 - s_{21}/x_2 - s_{22}/x_2). \tag{4}$$

Let us convert these terms to elasticities. Letting $\epsilon_{ij} = (p_j/x_i)(\partial x_i/\partial p_j)$, equation (5) becomes :

$$\partial(x_1^U/x_2^U)/\partial t = (x_1/x_2)(\epsilon_{11}/p_1 + \epsilon_{12}/p_2 - \epsilon_{21}/p_1 - \epsilon_{22}/p_2). \tag{5}$$

From Hicks's third law, $\Sigma_{j=1}^{n} p_j s_{ij} = 0$ and hence dividing by $x_i$ yields

$$\begin{aligned} \epsilon_{11} + \epsilon_{12} + \epsilon_{13} = 0 \text{ and} \\ \epsilon_{21} + \epsilon_{22} + \epsilon_{23} = 0. \end{aligned} \tag{6}$$

Substituting these expressions for $\epsilon_{12}$ and $\epsilon_{22}$ in equation (6), we have :

$$\partial(x_1^U/x_2^U)/\partial t = (x_1/x_2)[(\epsilon_{11} - \epsilon_{21})(1/p_1 - 1/p_2) + (\epsilon_{23} - \epsilon_{13})(1/p_2)]. \tag{7}$$

Equation (8) shows the implication of Alchian and Allen's proposition. Since $x_1$ is the higher-quality good, $p_1 > p_2$, and thus $1/p_1 - 1/p_2 < 0$. Also, $\epsilon_{11} < 0$ since own price elasticity is negative and $\epsilon_{21} > 0$ since two qualities of the same good are presumably substitutes [5]. Hence, the first term in the square brackets on the right hand side of equation (8), the direct substitution effect, must be positive. The last term, however, the interaction effect of $x_1$ and $x_2$ with $x_3$, $(\epsilon_{23} - \epsilon_{13})$, is mathematically indeterminate.

Alchian and Allen's proposition is that $\partial(x_1^U / x_2^U) / \partial t > 0$. Hence, this equation holds when either (1) only the first term is the entire expression in equation (8) (that is, a two-good world is assumed, as demonstrated by Gould and Segal (1969)), or (2), the higher and lower-quality goods interact in the same manner with the composite good $x_3$, that is, that $\epsilon_{13} = \epsilon_{23}$ or $\epsilon_{23} > \epsilon_{13}$.

The "shipping the good apples out" problem was conceived of in a situation where a higher-quality good, $x_1$ , and a lower-quality version of the same good, $x_2$ , are fairly close substitutes. It is not necessary that the goods be "higher" and "lower" quality versions of the same good, however, as long as they can be viewed as fairly close substitutes, where we can expect relatively high absolute values of $\epsilon_{11}$ and $\epsilon_{21}$, making the first term, $\epsilon_{11} - \epsilon_{21}$, in equation (8) relatively large. Moreover, the closer substitutes $x_1$ and $x_2$ are, the smaller their interaction with the composite commodity $x_3$ becomes, making the absolute values of $\epsilon_{13}$ and $\epsilon_{23}$ small. This means that the second term, $\epsilon_{23} - \epsilon_{13}$, in equation (8) will tend to be small.

Therefore, equation (8) can be approximated by the first term in the square brackets as an empirical matter :

$$\partial(x_1^U/x_2^U)/\partial t \approx (x_1/x_2) \cdot (\epsilon_{11} - \epsilon_{21})(1/p_1 - 1/p_2). \tag{8}$$

Thus when $x_1$ and $x_2$ are close substitutes, as an empirical matter, Alchian and Allen's proposition will hold ; that is, consumption of the higher-quality good should rise relative to that of the lower-quality good, if the same fixed cost is added to the price of both goods.

4. In this case, $\partial x_1/\partial t = \partial x_1/\partial p_1 + \partial x_1/\partial p_2 = s_{11} + s_{12}$ ; $\partial x_2/\partial t = \partial x_2/\partial p_1 + \partial x_2/\partial p_2 = s_{21} + s_{22}$.
5. In general, $\epsilon_{ij} > 0$ if $i$ and $j$ are substitutes, $\epsilon_{ij} < 0$ if complements, and $\epsilon_{ij} = 0$ if unrelated.

*2.3 The Umbeck Formulation*

Another formulation of Alchian and Allen's proposition is derived by Umbeck (1980). He points out that the Borcherding and Silberberg formulation is not useful in applying the proposition beyond the case of transport cost, because their $t$ variable is assumed to be a non-economic good. He argues that only transport costs and taxes qualify as such "goods". Furthermore, he suggests that, rather than viewing such a fixed charge as an addition to price, it should be thought of as an "entrance fee".

Consider an individual with a linear and compensated demand curve for apple juice as illustrated in Figure 2. Assume that the marginal cost of producing a unit of apple juice is constant at OC and that all transaction costs are zero. Also, suppose that consumer demands are homogeneous across consumers. The shaded area, ABC, thus represents consumer surplus.

In a two-part tariff scheme involving an admission fee, customers are asked to pay a lump-sum fee for the right to buy any quantity of the good, which has a uniform price. Amusement parks, for example, charge an entrance fee before any service is offered, although there is no connection to the cost involved in letting a customer enter the park. In this case the profit-maximizing owner of the park charges an entrance fee equal to the customer's consumer surplus (Phlips, 1983, pp. 160-163 and Pindyck and Rubinfeld, 1989, pp. 389-393).

Umbeck suggests viewing the "shipping the good apples out" proposition as an example of such two-part pricing. The good demanded is apple juice and the entrance fee is what is charged for access to the juice (the skin). From Figure 2, the seller can charge up to ABC, the consumer surplus, for the right to purchase apple juice and then charge one price, OC (the marginal price), per unit.

In the case of one time period, the situation is as depicted in Figure 2. However, when we consider more than one time period, the situation changes. Assume that the quantity which this individual purchases in each time period is inversely related to the quantities which she expects to purchase in the following time periods. In order to minimize the per unit cost, the wealth-maximizing consumer will reduce the number of times she buys apple juice and buy more juice each time.

With this background, consider the Alchian and Allen proposition as follows. Suppose we have a higher-quality apple, $x_1$, and a lower-quality apple, $x_2$, with prices $p_1$ and $p_2$ respectively. Also assume that the price $p_1$ is double $p_2$ and that the higher-quality apple has two times as much juice as the lower-quality apple.

Now the apples are shipped out to another location at a cost of $t$ per apple, producing a set of prices $p_1 + t$ and $p_2 + t$. Payment of the fixed cost $t$ is always required in order to purchase an apple, a payment for the right to buy. Thus it can be regarded as an "entrance fee" because it fits the requirements of a fixed charge. It is an essential condition for obtaining access to both apples and it has no value of its own. Because the marginal price of juice has not changed and we have assumed compensated demand curves, those consumers who continue to buy apples will buy the same amount of juice. However, they will buy fewer apples in order to minimize this entrance fee, and therefore they will switch to the higher-quality apple with more juice. According to Umbeck (1980), this formulation avoids the problem raised by Gould and Segall that substitution effects with some third good might destroy the "shipping the good apples out" effect.

Umbeck concludes, then, that the consumer increases the relative consumption of "high quality" to "low quality" apples not because their relative prices change but, rather, because this economizes on the payment of the entrance fee. However, he argues that this reasoning does not apply to the restaurant meal example because there is no comparable entrance fee in that case. The services provided by the restaurant are unlike transportation services in the restaurant or in the household : "...a nice, air-conditioned restaurant with a friendly waitress serving the food, a cook preparing the food, and a dishwasher to clean up afterward all have a value of their own." (Umbeck, p. 202). If restaurants have a comparative advantage (over the household) in providing some of these services, the consumer will purchase more of them in the restaurant than at home. However, since there is no effect on the relative prices of the food items, there is no reason to believe that the ratio of "high quality" to "low quality" food items consumed will be different at the restaurant than in the home [6].

Thus, there are two views of the issue. If that portion of the price of a restaurant meal in excess of what the consumer would pay to eat the same meal at home can be thought of as analogous to a transportation cost, affecting relative prices,

6. That is, unless the substitutional relationships in consumption between services and the "high quality" food is different than that between services and the "low quality" food.

then the "shipping the good apples out" proposition will lead to the prediction that the ratio of "high quality" (higher priced) food items to "low quality" items consumed in restaurants will exceed the ratio pertaining to home comsumption [7]. The alternative hypothesis is that the services provided by a restaurant are not analogous to transportation services and, thus, the "high quality" to "low quality" ratio will be the same in the restaurant and the home.

With these two alternative views of the Alchian and Allen proposition, it is appropriate to discuss ways to distinguish between them empirically. In so doing the literature on consumer response to block pricing is helpful in developing the empirical specification so that it provides a critical test of competing hypotheses.

## 3. ECONOMETRIC SPECIFICATION

In the neoclassical theory of consumer behavior, the determinants of quantity demanded are the price of the good, prices of related goods, income, and tastes. Hence, the demand relationship can be represented simply by the following single equation model :

$$Q = f(p_1, p_2, Y). \tag{9}$$

In the Alchian and Allen proposition, the demand function will be further affected by other variables such as the transport cost $t$. In this case the demand function would be represented by :

$$(x_1/x_2) = f(p_1, p_2, Y, t), \tag{10}$$

where :

$Q$ = the ratio of the consumption of the higher-quality good, $x_1$, to that of the lower-quality good, $x_2$ ;

$p_1$ = the price of the higher-quality good ;

$p_2$ = the price of the lower-quality good ;

$Y$ = consumer's income ; and

$t$ = the unit transport cost.

We now have two alternative formulations of Alchian and Allen's proposition. Under the formulation by Borcherding and Silberberg, the "fixed" cost (added equally) causes the price ratio of the two goods to change ; consequently, consumption of the higher-quality good increases relative to that of the lower-quality good. In this formulation, the demand equation (the ratio of the consumption of the higher-quality good to that of the lower-quality good) is :

$$(x_1/x_2) = f[(p_1+t)/(p_2+t)] \tag{11}$$

where :

$x_1/x_2$ = the ratio of the consumption of the higher-quality good, $x_1$, to that of the lower-quality good, $x_2$ ; and

$(p_1+t)/(p_2+t)$ = the price ratio of $p_1$ to $p_2$ with transport cost $t$ added equally

On the other hand, under Umbeck's formulation, the consumption ratio of the two goods is only affected, if at all, through block pricing, not by the change in price ratio but by the cost of services. Hence, the demand function (the consumption ratio of the higher to the lower-quality good) would be defined as :

7. Using Umbeck's reinterpretation of the Alchian and Allen proposition, one could argue that the charge for restaurant services is like an entrance fee in the same sense that charging a single price for a package that contains a razor and razor blades can be viewed as a case of multi-part pricing. The consumer pays the entrance fee associated with the razor plus a price per blade. Without blades, the razor is of little value to the consumer, although it could be priced independently of the blades. The higher the fixed charge the more likely is the consumer to purchase "high quality" (i.e. longer-lasting) blades in order to minimize payment of the entrance fee. Viewed this way, the higher the price charged for restaurant services the less frequently the consumer will dine in restaurants but the more likely that, when she does, she will select higher quality food items.

$$(x_1/x_2) = f(p_1/p_2 , t) \quad (12)$$

where :

$x_1/x_2$ = the ratio of the consumption of the higher-quality good, $x_1$, to lower-quality good, $x_2$ ;

$p_1/p_2$ = the price ratio of $p_1$ to $p_2$ ; and

$t$ = the unit cost of restaurant services.

In the Borcherding and Silberberg formulation, consumers respond to the new price ratio with the fixed cost added equally, $p_1 + t/p_2 + t$ . In the Umbeck model, however, the consumer's behavior does not depend on the new price ratio, but on the amount the payment of the service charge subtracts from her income and the substitutional relationships between the restaurant services and each of the two goods. The substitutional relationship is not observable, but the service charge is.

To test the competing hypotheses we draw on a similar debate in the literature on water demand where the issue is whether consumers choose on the basis of average or marginal prices, when faced with a multi-part pricing arrangement (Gibbs, 1978 ; Foster and Beattie, 1981 ; Opaluch, 1982 ; and Polzin, 1984). To test these competing hypotheses Opaluch suggests a single equation econometric model :

$$Q = B_0 + B_1P_x + B_2MP + B_3(D/Q) + B_4(Y - D), \quad (13)$$

where :

Q = total purchases of the good ;

$P_x$ = a price index for other relevant goods ;

MP = the block price of Q, *i.e.* marginal price ;

Y = consumer's income ; and

D = the expenditure difference between the actual utility bill and what the bill would have been if all Q units had been priced at the marginal price [8].

Applying Opaluch's model to our formulation of Alchian and Allen's proposition, we have :

$$(x_1/x_2) = \beta_0 + \beta_1 t + \beta_2(p_1/p_2) + \beta_3(p_1+t/p_2+t) \quad (14)$$

where :

$x_1$ = higher-quality good ;

$x_2$ = lower-quality good ;

$p_1$ = the price of $x_1$ ;

$p_2$ = the price of $x_2$ ; and ;

t = the transport cost (or entrance fee).

Following Opaluch's hypothesis testing procedures, if consumers respond to the change in price ratio between $p_1$ and $p_2$ when the fixed cost is added equally, then $\beta_2 = 0$, and the demand model can be written as Borcherding and Silberberg's formulation :

$$(x_1/x_2) = \beta_0 + \beta_3 (p_1+t/p_2+t). \quad (15)$$

8. D is Nordin's lump-sum income effect term. Average price can be shown as : AP = MP + D/Q ; therefore, if $B_2 = B_3$, this equation becomes : $Q = B_0 + B_1 p_x + B_2AP + B_4(Y - D)$.

Alternatively, if consumers react to an entrance fee, as in block pricing, then $\beta_3 = 0$, and equation (15) reduces to Umbeck's formulation :

$$(x_1/x_2) = \beta_0 + \beta_1 t + \beta_2(p_1/p_2) \tag{16}$$

Thus, to compare the validity of these alternative behavioral models, the following tests can be employed.

Test 1 :

$H_0 : \beta_1 = 0;$
$H_A : \beta_1 \neq 0$

Test 2 :

$H_0 : \beta_2 = 0 ;$
$H_A : \beta_2 \neq 0.$

Test 3 :

$H_0 : \beta_3 = 0 ;$
$H_A : \beta_3 \neq 0.$

The possible outcomes from these two tests and their implications for Alchian and Allen's proposition are summarized in Table 1. Outcome 1 suggests that consumers react to the price ratio between $p_1$ and $p_2$ with $t$ added equally ; i.e. Borcherding and Silberberg's formulation is correct. Outcome 2 proposes that consumers respond not to the price ratio but to the entrance fee, so that Umbeck's formulation is correct. Outcome 3 would indicate that the consumers do not react to price at all. Outcome 4 is indeterminant. As Opaluch (1982) states, this indeterminancy may simply be a reflection of weak data. It may also arise if some consumers react to the price ratio between $p_1$ and $p_2$ with $t$ added equally while others react to an entrance fee. Alternatively it might support a more general model of consumer behavior.

## 4. PRELIMINARY RESULTS AND CONCLUSIONS

The econometric model specified above was run using data from a Japanese restaurant for the period April-December 1991. Price ratios between salmon and beef, salmon and pork, beef and chicken, and beef and pork were tested. Several alternative models, including and excluding some of the explanatory variables, were tested.

Unfortunately, it is too early in the progress of our empirical work to draw any conclusions about the validity of either of the alternative formulations discussed above. Results to date show high correlation between the independent variables, indicating a multicollinearity problem within the models as currently specified. In addition, due to the low number of observations as compared with the number of variables, degrees of freedom are very low. Calculated "t" statistics on most of the explanatory variables were very low, indicating significance only at very low levels of confidence.

As these results are very preliminary, this should be regarded only as an interim report on the empirical testing of the alternative hypotheses, which is still in progress at this writing. Plans to improve the results so that conclusions can be drawn include experimenting with other functional forms such as the log linear ; eliminating some of the variables which appear to be highly correlated ; indexing variables through a weighting system to reduce multicollinearity ; and using a generalized rather than ordinary least squares analysis. If these methods fail to correct the problems of the model, we will need to seek a data set with more observations ; a longer series which covers a time period where more change in the price ratios is observed should provide more conclusive results.

Our goal in this paper has been to provide the theoretical background for a discussion of how consumers respond to differences in prices, and to devise an econometric test of several alternative hypotheses about these responses. We hope soon to be able to provide more definitive test results which will help to determine whether consumers respond to a change in the ratio of prices they face for two options, or whether in fact this difference in ratio is not perceived as such and does not affect consumer behavior. If no evidence is found to support the application of Alchian and Allen's theory (as formulated by Borcherding and Silberberg), future research may focus on how Umbeck's concept of the entrance fee

as a separate economic good, with a value of its own, can be tested with regard to consumer choices of seafood vs. competing goods in restaurants and retail outlets. The results of these tests will increase our understanding of consumer responses and perceptions. In particular we should have a better sense of what affects seafood consumption both in, and away from, the home.

# Cross-Hedging Fishmeal with Soybean Meal Futures

**Tomislav Vukina and James L. Anderson**

Department of Resource Economics, University of Rhode Island, Lippitt Hall, Kingston, RI 02881, USA

ABSTRACT

*The paper explores the link between the fishmeal and the soybean meal markets and generates price forecasts using the state-space approach to modeling vector-valued time series. The study illustrates how fishmeal producers, could significantly increase their profits by utilizing the information from the forecasting models to construct a selective hedging strategy where the futures positions are established in soybean meal contracts.*

## 1. INTRODUCTION

This study establishes the link between the fishmeal market and the soybean meal market. It shows that an appropriate hedging strategy can be developed even for the commodity for which a viable futures market does not exist, provided that futures market exist for a close substitute commodity. The soybean meal has a full futures market system, whereas the fishmeal market, although closely tied to the soybean meal market, is entirely based on spot pricing. The relationship between the two markets presents an opportunity for fishmeal producers to cross-hedge their cash fishmeal positions with the use of soybean meal futures contracts.

The central hypothesis of this paper is that potential positive returns are available to traders who are able to outperform other traders in predicting price movements. The objective of the study is to explore the linkage between the fishmeal and the soybean meal markets, generate price forecasts, and combine the information from forecasting models with a selective hedging strategy that would increase revenues of the fishmeal producers.

While examining the forecasting ability of futures markets, most of the previous studies compared cash prices with lagged futures prices (e.g. Kofi 1973). Rather than using futures market prices to forecast future cash prices, the method employed in this study exploits dynamic relationship between contemporaneous time series of cash and futures prices and then forecast them simultaneously. The approach is based on a multivariate time series state-space modeling technique that has been proposed by Aoki (1987 ;1990). In order to test the quality and reliability of the forecasts, a

hedging signals generating model is constructed. Based on the forecasts, the model signals the hedger when to initiate the futures market position to counterbalance his predetermined cash position. The results are compared to those obtained by routine hedging and cash marketing strategy.

## 2. FORECASTS-BASED CROSS-HEDGING STRATEGY

The production of fishmeal in the United States amounted to 321,898 tons in the year 1988, 280,554 tons in 1989, and 264,871 tons in 1990 (U.S. Dept. of Commerce). Valued at the midmonth current Atlanta cash prices, the industry's gross revenue was $168 million in 1988, $116 million in 1989, and $92 million in 1990. The fishmeal producers are limited in formulating marketing strategies because there is no fishmeal futures market that can be used as an inventory management and pricing tool. In order to overcome this drawback, fishmeal producers can cross-hedge their cash positions using futures of a close substitute commodity (soybean meal). Cross-hedging should work if the behavior of fishmeal spot price is sufficiently similar to the behavior of the soybean meal futures price to produce a contemporaneous correlation coefficient significantly different from zero.

Fishmeal is a high-value, high-protein animal feed ingredient that is manufactured from the whole fish and fish offal. The demand for fishmeal is derived from its use in mixed feeds, primarily for poultry, livestock and farmed fish. The production of fishmeal is, given an ample and regular supply of fish at an acceptable price, a continuous process. The core of the production process is the separation of raw material into fat-free dry matter, oil and water. The duration of the process is typically 1-4 weeks, depending on the treatment of the freshly prepared meal (*curing* or anti-oxidant stabilization). Correct treatment will produce a product which can be stored indefinitely under dry conditions without deterioration (FAO, 1986).

The price of fishmeal is largely determined by the price of competing protein feeds, especially soybean meal. Because fishmeal contains certain growth promoting factors appreciated by the farmers, its price generally commands a premium. The primary industrial fish used by the United States fishmeal producers is menhaden, which usually accounts for more than 75 percent of the total annual production, and yields meal with a protein content of about 60 %.

Soybean meal is the dominant protein supplement used in livestock and poultry feeds, but it also can be found in baby foods, bakery goods, and various specialty food items, as well as in many industrial nonfood products. Soybean meal faces competition from various animal and vegetable products. In the animal category, fishmeal and tankage (the dried by-product of meat packing) compete with soybean meal. Vegetable oilseed meals include those produced from rapeseed, cottonseed, flaxseed and sunflower seeds. When the price of one of these products is more favorable than the price of soybean meal, there is a tendency toward substitution. In some uses, soybean meal has no substitute because of its high protein content and its suitability for feeding to all types and ages of livestock and poultry.

The model developed in this paper is different from the traditional approach to hedging because it is not based on any of the optimality criteria. In other words, an economic agent is neither maximizing nor minimizing any of the objective functions by choosing the decision variables at his disposal. Rather than being descriptive (positive), the model of this chapter is normative, i.e. it tells the hedger what to do, by generating *HEDGE* or *NO HEDGE* signals.

It has been shown that routine hedging strategy (forward pricing of the entire cash position) reduces risk (Peck 1975). However, this strategy frequently results in foregone potential positive returns from the correctly predicted movements in prices. A more sophisticated strategy, which incorporates the information from forecasts, can conceptually both increase expected utility and reduce risk relatively to strictly cash marketing or routine hedging.

The approach uses contemporaneous cash and futures prices, estimates the parameters of the multivariate time series state-space model, and then generates out-of-sample forecasts. Thus, rather than using futures market prices to forecast future cash price, as most of the previous studies have done, the proposed method exploits dynamic relationship between contemporaneous time series of cash and futures prices, and forecast them simultaneously.

Based on Brandt (1985), a simple rule for selective hedging is utilized. The producer (seller) will hedge and stay hedged as long as the current futures market price is greater than forecasted cash price, or will lift the hedge and remain unhedged as long as the cash price is forecasted to be higher than the current futures market price. However, any analysis which compares futures prices with cash prices must also adjust for the basis, particularly if the hedger has no intention of

delivery. Basis, as the difference between the futures price and cash price, has traditionally been more stable over time than cash or futures prices and is hence easier to forecast. Therefore as an operational rule for selective hedging, the producer (seller) will hedge and stay hedged whenever :

$$F_t - B^*_{t+1|t} > P^*_{t+1|t}. \tag{1}$$

Using the definition of the basis, expression *(1)* becomes :

$$F_t - (F^*_{t+1|t} - P^*_{t+1|t}) - P^*_{t+1|t} > 0 \tag{2}$$

$$F_t > F^*_{t+1|t}$$

where $F_t$ is the period $t$ quotation of the selected futures contract price, $F^*_{t+1|t}$ is the next period forecast of the same futures contract price, $P^*_{t+1|t}$ the next period forecast of cash price and $B^*_{t+1|t}$ is the next period basis forecast ; all forecasts based on information available at time $t$. The intent is to evaluate, *ex-post*, whether sellers (producers), by exercising the above selective hedging strategy, could have received a higher price for their commodity compared to sellers who used routine hedging procedure or cash marketing strategy only.

## 3. PERFORMANCE OF THE FORECASTING MODELS

The state-space models used in this paper consist of the state and the observation equations :

$$\begin{aligned} x_{t+1|t} &= Ax_{t|t-1} + Be_t \\ y_t &= Cx_{t|t-1} + e_t \end{aligned} \tag{3}$$

where $\{y_t\}$ to be modeled is a $m$ -series, zero-mean, weakly stationary vector-valued Gaussian stochastic process with auto-covariance sequence $\{\Gamma_j\}$. Matrices A, B, and C are parameters of the system, $x_t$ is a vector of $n$ unobservable states that are minimal sufficient statistics for the history of the process $\{y_t\}$, and innovations $\{e_t\}$ are white noise. The subscripts on x refer to the conditional expectation of x in the period of the first subscript given the information set at the time of the second subscript.

The estimates of the system matrices, together with the estimate of the initial state $x_1$ enable a straightforward generation of the in-sample and out-of-sample forecasts. In this paper, a departure from the standard Aoki's procedure for estimating the parameters of the covariance state-space model is made, and an alternative procedure based on Kung (1978 : 705-714) and Vaccaro (1986 : 105-112) is used. Additionally, the frequently suggested backcasting method for estimating the vector of initial states is abandoned, and the least squares solution for the vector of initial states is found. The details of the entire estimation and forecasting procedure can be found in Vukina (1991). The formula for the calculation of the out-of-sample forecasts is given by :

$$\hat{y}_{t+k+1} = CA^k x_{t+1} + \mu \tag{4}$$

Since centered data are used, the mean of the series $\mu$ which was initially subtracted from each observation, has to be added back to equation *(4)* to obtain the forecast of the same order of magnitude as the actual data. If $k=0$, expression *(4)* reduces to one-step-ahead forecast ; $k=1$ generates $\hat{y}_{t+2}$, etc. In case of a bivariate model, where for example, contemporaneous cash and futures prices are modeled together, vector $\hat{y}_{t+1}$ consists of the next period out-of-sample forecasts of the cash price (P*), and futures price (F *).

The data set used in this study covers the five year period between June 5, 1986 and May 23, 1991, for a total of 260 weekly observations on fishmeal cash and soybean meal futures prices (see Figure 1). The fishmeal prices are midweek observations of Atlanta menhaden fishmeal spot prices as available from *Feedstuffs*. Prices are quoted in dollars per short ton. Since the majority of the U.S. production is taking place in the South, the Atlanta price is the most frequently cited

in business periodicals as the U.S. domestic price. The average price in this period was $404.25 with the standard deviation of $67, the minimum price of $290, recorded in June/July 1986, and the maximum price of $620, recorded in June of 1988.

The soybean meal data were obtained from various issues of *The Wall Street Journal*. The futures data are Thursday closing prices for the Chicago Board of Trade soybean meal December contract. Trading unit is 100 short tons, and prices are quoted in dollars and cents per ton, with a minimum fluctuations of $0.10 per ton ($10.00 per contract), basis f.o.b. railcars, bulk, Decatur, Illinois. There is only one deliverable grade of meal with a minimum of 44 % protein content. The December contract was chosen because it is the most actively traded soybean meal contract for which the continuous series of prices exists throughout the year. The first trading day in December was used as the switching point between the expiring and the incoming December contract. The average price of the CBOT December contract for the entire period was $187.75, with the standard deviation of $33. In the same period, the average Decatur soybean meal cash price was $191.73.

The average fishmeal to soybean meal cash price ratio was 2.12, and was fairly stable throughout the period with the minimum value of 1.72, and the maximum value of 2.54. The contemporaneous correlation coefficient between the Atlanta fishmeal spot price and CBOT December soybean meal futures is 0.8827 which is significantly different from zero at the 1 % significance level. The magnitude of the coefficient is relatively high, having in mind that for the same five year period, the correlation coefficient between Decatur soybean meal cash price and CBOT December futures price was only slightly higher (0.8931). The result justifies the use of the soybean meal futures for cross-hedging fishmeal cash positions.

Although analytically equal, expressions *(1)* and *(2)* can lead to three distinct forecasting models. In order to use hedging rule *(1)*, forecasts of basis and cash price in period $(t+1)$ are needed. Bivariate time series may consist of cash and futures prices to give the basis forecasts indirectly as the difference between futures price forecast and cash price forecast. Alternatively, historical data for a particular location basis can be calculated by subtracting cash from futures prices, and then modeled together with cash prices. Using this approach, basis forecasts would be generated directly along with the cash price forecasts. Finally, the third alternative based on expression *(2)* would involve scalar time series model of futures market prices only.

All three models are initially estimated with the first 104 observations, and one-step-ahead, out-of-sample forecasts are generated. In the following step, an additional actual observation (the 105th) is added to the existing pool of data points to update the system matrices, thus generating the new one-step-ahead forecast. The same procedure is repeated 156 times. All models in each of the 156 rounds are estimated with the most distant auto-covariance lag of $k=2$. The number of states for the bivariate *cash and futures prices* model equals 2, while the second bivariate model *(cash and basis)* and the scalar *(futures prices)* model are estimated with one state $(\tilde{n}=1)$. The situation when an estimated covariance model does not define a positive sequence occurs occasionally, and is successfully dealt with using the procedure developed in Vaccaro and Vukina (1991). The forecasts generated by all three models are plotted in Figures 2-4.

In order to discuss alternative models it is necessary to have a criterion by which the performance of the predictors is measured. The usual criterion is the mean square error (MSE) or root mean square error (RMSE). However, in order to compare the models which attempt to model different processes (time series), we also use the mean absolute percentage error (MAPE) which is the measure of the average percentage deviation of the forecast from its corresponding actual value, and is therefore dimensionless. The model which generates forecasts with smallest statistics is according to the above specified criteria the most favorable one. The comparative forecasting statistics are presented in Table 1.

According to both MSE and MAPE criteria, the best forecasting result of the fishmeal cash price is obtained with two-channel cash and futures model. The average percentage deviation of the forecast from its corresponding actual value is 2.16 %. The forecasts of the soybean meal futures price generated by the scalar model, with MAPE statistics equals 2.43 %, slightly outperform the forecasts generated by the bivariate model. The basis forecasts yield more modest result, with the mean absolute percentage error of 6.3 %.

However, from the perspective of this study, a more valuable criterion for forecasts evaluation is their usefulness for different hedging strategies. This is the issue addressed next.

## 4. SIMULATION RESULTS

Although the data on fishmeal cash prices and soybean meal futures prices are available from June 5, 1986, the actual trading simulation starts on June 2, 1988 (the first 104 observations were used for initial estimation), and ends on May 23, 1991. The entire trading period is divided into six 6-months long sub-periods (see Table 2 and Table 3). At the end of each sub-period all outstanding cash and futures positions have to be liquidated. In the first week of each sub-period a hypothetical fishmeal producers (dealer) starts with 100 tons of fishmeal valued at the prevailing spot market price $P_0$, and sells his inventory at the price that prevails on the last trading day of the same period $P_T$. The price $P_0$ can be treated as the accounting unit cost of production, i.e. the price that would have been obtained had the product been ready for sale in the first week of the sub-period under consideration. In order to keep the problem tractable, the possibility of selling the inventory at any point in time between the two specified dates is ruled out. Since storage and handling costs were ignored, the difference in cash price between the two dates multiplied by the quantity (100 tons) is considered as profit from cash marketing.

During the period when he is long in cash market, the producer (dealer) faces three options :

i) to remain unhedged throughout the period ;

ii) to hedge the entire fishmeal inventory using soybean meal futures, and remain hedged throughout the period (routine strategy) ;

or iii) hedge selectively using the operational rule specified in expressions *(1)* or *(2)*.

For the sake of simplicity, it is further assumed that opportunity costs of capital (interest payments) are negligible and that hedging costs consist only of fixed costs per contract (brokerage fees). Because of the intraperiod price variation, margin calls present a distinct possibility and could potentially cause a cash flow problem for the hedger. However, since the likelihood of margin calls cannot *a priori* be considered any greater than the likelihood of margin surpluses, which would yield a favorable return to the hedger, the above assumption is probably not too restrictive.

If the dealer decides to remain unhedged (i), he assumes the entire risk of price variation, and his end-of-period total profit consists of profits from cash marketing only.

Routine hedging strategy (ii) involves selling short the entire inventory. The hedge is placed (one December soybean meal contract is sold) the first week of each sub-period, and lifted (one December contract is bought back) the last week of the same period. Under the routine scenario, the profit per one round of hedging is equal to the difference between the futures market quotation on the day when the hedge is placed and the day when it is lifted, multiplied by the quantity hedged (1 contract=100 tons), and corrected for the fixed cost of hedging per one contract, and per one roundturn.

Selective hedging strategy (iii) also involves selling short the entire inventory. However, the hedge will be placed only when the action is signaled by the forecasts, i.e. when the condition specified in *(1) or (2)* is fulfilled. More specifically, every week the parameters of the model are estimated, the prices for the next week (cash, futures, basis) are forecasted and the decision whether to hedge or not is made. The following week, the previous week prices are added to the pool of the existing data, the parameters of the model are re-estimated and the new one-step-ahead forecasts are made together with the new decision.

The performance evaluation of the forecasting approach to hedging for the period from June 2, 1988 to May 23, 1991, is summarized in Table 2. Measured by the combined percentage of correct *HEDGE* and *NO HEDGE* signals, both multivariate models outperform the scalar model. Additionally, the bivariate *cash and futures price* model clearly outperforms the bivariate *cash and basis* model with respect to both correct *HEDGE* and *NO HEDGE* signals.

The measured trading profits clearly show the superiority of the forecasts based selective hedging strategy over the routine hedging or cash marketing schemes. Trading is simulated with a fixed cost of $50.00 per contract per roundturn. Notice that once the hedge is in place, it is costless to continuously remain hedged in the same number of contracts afterwards. Only after a disruption of the continuous sequence of *HEDGE* signals has occurred (hedge was lifted), the establishment of the new position in the futures market would require additional expenditure. In other words, if the position in the futures market is already established, the cost of retaining the same position continuously through time is zero. Costs of hedging in our simplified model are associated only with changing the position in the futures market or entering it for the first time.

As seen from the Table 3, when profits are considered, both multivariate models are outperformed by the scalar model. The average profits in the entire period under consideration (all 6 subperiods) generated by the scalar model are 118.18 % larger than those obtained by the routine hedging strategy. Bivariate *cash and futures* model generates on average 63 % larger profits than the routine strategy, which was enough to outperform the *cash and basis* model with the profits of 28 % above the routine strategy.

The number of roundturns per period is fairly small. In fact, in the scalar model, the futures market was entered only one or two times. In case of one roundturn per period, the number of weeks a hypothetical trader was hedged corresponds to the number of *HEDGE* signals from Table 2. For example, it turns out that during the period from December 7, 1989 to May 31, 1990, the trader which used forecasts generated by the scalar model, entered the futures market once, and remained hedged for 4 consecutive weeks, making the profit of $1,010. In case of the multiple entry-exit, the average duration of the short hedge can be calculated as the ratio between the number of *HEDGE* signals and the number of roundturns.

## 5. CONCLUSIONS

Numerous simplifying assumptions are made in this paper. A simple decision rule is used ; no attempts are made to determine the optimal hedging ratio in the static framework, let alone in the intertemporal framework ; and opportunity costs of capital and cash flow problems are ignored. Also, no attempt is made to incorporate hedging strategy into the broader framework of optimal inventory management.

The objectives of the research can be summarized as follows :

i) to explore the linkage between the fishmeal and the soybean meal markets, and to forecast prices using an approach to modeling multivariate time series based on linear systems theory ;

ii) to utilize the information from the forecasting models to construct a selective hedging strategy ; and

iii) to test the performance of the forecasts by ex-post evaluation of the various hedging schemes.

The research results show the usefulness of state-of-the-art time series forecasting techniques in marketing fishmeal. Even without an established fishmeal futures market, the producers could still hedge in close substitute commodity with the viable futures market, and could significantly improve their marketing performance by combining the information from the forecasting models with an appropriate hedging strategy. With the use of personal computers, fishmeal producers can use the developed methodology as an effective marketing tool to improve profitability and sustainability of their operations.

A possible extension of this research lies in the possibility of adapting the forecasting methodology to model population dynamics of fish stocks which can help better management and utilization of limited marine resources.

# Market Analysis Institutional Behaviour and Marketing of Fish in Portugal

**Salviano Cruz**

Estudos Económica Sociais. Rua Duque De Palmela, 27, 4°E 1200 Lisboa, Portugal

ABSTRACT

*Production of fish (landings) has been declining sharply since 1963, which has caused large imports and exports of fresh and frozen fish. Landings from continental waters have been strongly declining, which has provoked a rise in a new search for foreign fishing grounds and new sources of fishing supplies.*

*Prices of fish have increased sharply both in the producer price and to the consumers, due to monopolistic practices and abuse of economic power.*

## 1. DECLINE OF FISH CATCHES AND LANDINGS IN PORTUGAL.

The main tendency has seen a strong decline of fish catches and landings in Portugal over these years, both in total and also for the main species. Catches of fish have declined from 424.982t in 1965, to 343.942t in 1979, to a peak minimum of 273.681t in 1985. From this year on landings have picked up, continuing to rise to 403.303t in 1986, declining again to 385.600t in 1987, with a continuous decline in the years 1988 to 350.300 and 331.000t in 1989, see tables 1 and 3. Table I, indicates landings for 22 out of 25 main species landed in 1965, 1979, 1985 and 1989, indicating rise in prices.

We can see the main decline of various species including cod, which from landings of 71.280 t in 1965 to 41.450t in 1979, with a rise to 16.721t in 1979 increasing to 19.342t in 1989. From this table we can verify the importance which the cod fish industry represents in the species landed in Portugal. In 1965 this species was second only to sardine which landings were 137.931t. In 1979 landings of sardine was 101.150t occupying first place in the structure of the wholesale market in Portugal.

In 1989 sardine landings were 91.263t while cod landings were 19.342t, declining from second to third place after horse makerel (carapau) whose landings declined from 27.678t in 1965 to 26.735t in 1989.

Some species like dentex and sea bream are declining or disappearing. However new species like secabard (peixe espada) have appeared in relatively large quantities as "white" or "black". In 1965 landings of these species were 5.623t, rising to 7.747t in 1979. In 1989 landings were 5.461t for white and 3.552t for black. White occurs in the central and southern fishing zones of Portugal, while black "peixe espada" is mainly caught around the Sesimbra area located 50 kilometres south of Lisbon and also in the Madeira fishing grounds with 2.724.2t in 1988 and 2.476.5t in 1989.

Cod landings, have been declining strongly since 1965 and particularly, after the fixing of the 200 mile limit by Canada, Norway and Iceland and other countries. This makes Portugal a large importing country in place of a surplus fishing country before the 1960's, see table 3 Catches of the Portuguese Fishing Fleet 1986-1989.

In 1965 Portugal had a production of landings of 71.280t of cod, this declined to 41.450t in 1979, reducing to 16.721t in 1985, but increasing in 1989 to 19.932t.

Currently, Canadian fishing organizations are opposing the foreign fleets of Portugal and Spain alleging that these two fleets have destroyed the stocks of cod in the Canadian fishing grounds.

This accusation has no foundation, as the canadian fleet has also contributed to this situation of stock depletion by over fishing. Moreover, Canada needs to reorganize its own cod fishing industry along the coast where monopoly oligopolies and oligopsonies prevail. It seems that Canada wants to hold the control of cod by dominating fishing trade of the world, through quotas which again is a violation of Article 852 and 862 of EEC.

## 2. QUANTITIES AND PRICES 1987 - 1989
## LANDINGS OF FISH IN CONTINENTAL PORTUGAL AND AVERAGE PRICES

Table II indicates landings for the main species during the years 1987/1989, with variations. Total landings in 1987 was 224.573t with an average price varying from Esc.159$47 in 1987 to Esc. 199.40 $ in 1989 for 217.177.4t.

European Anchovy, landings were 1.621.6t at prices Esc.273.20 $ in 1987 declining to .774.0t at prices Esc.216$0, in 1989 rising to 822.9t at Esc.334.60$ in 1989.

Horse mackerel, landings declined from 31.112t to 26.775t in 1989 prices incresead from Esc. 149.90 $ in 1982 to Esc. 180.30 $ in 1989.

Congre landings in 1987 were 1852t for Esc.314 ;40 $ increasing to 21204t in 1988 at Esc. 351.90 $ declining to 2078t at prices Esc. 356.30 $ in 1989.

Secabard, there are two types of this species : white and black.

Landings in 1987 were 3.328.7t at Esc.188.5, rising in 1987 varying from Esc. 122.60 $, to Esc. 159.20 $ in 1988 for 384.4t rising, to 3.552.7t at prices Esc. 185.50 $ in 1989. Secabard white, landings were 4.249.8t at Esc. 304.70 $ in 1987 rising to 4673t ; price rose to Esc. 332.90 $ in 1988, declining to 4531.7t at Esc. 376.30 $ in 1989. The main landings centre for these species is Sesimbra 3.521.2t for black secabard and 3.976.6t in 1989 see Table V.

Faneca landings were 4.298t at price Esc. 198.10 $ declining to 2.883 tons in 1989 at price Esc. 302.30 $. Sole landings were 1.550t at price of Esc.1.159.00 $ in 1987 declining to 988.3t in 1988 at prices Esc.1.195.80 $ rising to 1.200.01 at price Esc.1.155.50 $ in 1989.

Hake, landings were 8.595.5t at price Esc. 587.00 $, in 1987, in 1988 landings were 6.470.1t at price of Esc. 688.90 $ and 5.416.5t at Esc. 702.60 $ in 1989.

Rays, landings were 2.760.02t at Esc. 116.70 $ in 1987, declining to 2.201.49t at price of Esc. 147.20 $ declining to 1.874.7t price Esc. 218.20 $ in 1989.

Seabream, landings were 358.9t at price of Esc.1.146.90 $ rising to 463.7t at price Esc.1.314.80 $ in 1988, rising to 629t at a price of Esc.1.459.50 $, in 1989.

Sardines, finally, we come tot eh sardine ; the species with the largest landings 90.199.6t at a price of Esc. 31.70 $ in 1987, rising to 94.836.1t at Esc. 38.30 $ in 1988, and declining again to 91.236t at price Esc. 42.00 $.

Monkeyfish, landings were 2.088.1t in 1987 at price of Esc. 470.10 $/kg, declining to 1.911.7t, at price of esc. 593.80 $ and still declining to 1.837.9t at price of Esc. 611.10 $.

Tuna and similar landings in 1987 in the continent were 587.8 tons selling at Esc. 238.2/kg, rising to 638.9t at price of Esc. 239.90 $, in 1988 declining to 238.2t at Esc.238.50 $ in 1989.

Kolb landings in 1987 were 390.1t at price Esc. 653.30 $, declining to 284.1t at Esc.882.31. in 1989 18.257t at price Esc. 354.00 $.

Average price for tuna landed in Azores for 1989 were Esc. 110.00 $ per kg, 8.800t. In Madeira landings of tuna in 1988 were 1.728.9 at Esc. 212.90 $, landings in 1989 were 3.744.0t at an average price of Esc. 140.70 $ /kg. Major species in Madeira besides tuna was Peixe Espada Preto, secabard black, 2.724.2t at price Esc. 217.10 $ in 1988, and 2.476.5 in 1989 price of Esc. 225.60 $.

Sources : Recursos das Pescas Estatiscas vol. 3A-B Aug. 1991, vol 2A-B 1980 Oct 1989, Gabinete Estudos e Planeamento das Pescas.

In table 3 we can compare catches and landings for the period 1986/89 by species and main fishing grounds supplying Portugal. Statistics of table 3 for continental Portugal, Azores, Madeira and Spain refers to landings by species. We compare the quantities landed for the fishing grounds.

*CECAF.*

In this traditional Portuguese fishing ground covering Marrocos and Mauritania catches varied from 20.300t in 1986 to 17.600t. Morrocos and Mauritania catches varied from 20.300t in 1986 to 14.600t in 1988, and 18.72 in 1989, see TABLE III.

*Northern Atlantic.*

Northern Atlantic catches of fish declined from 103.200t in 1986 to 42.700t in 1988. and 32.239.3t in 1989 NATO fishing ground catches declined from 98.100t in 1986 to 49.760t in 1989. Major decline in catches was cod with 43.100t in 1986 to 13.600t in 1988, and 24.128.0t in 1989. Redfish catch also declined from full 32.500t to 19.100t in 1988 and 18.820t in 1989, catches of other species aslo declined from 22.400t to 8.200t, in 1988.

Norway/Svolbank production catches declined from 5.100t in 1986 to 2.869t in 1988, and 1.272.6t in 1989. The catch of cod was 3.500t in 1986 to 0.49t in 1988, and to 339.7t in 1989, see TABLE III.

*Southern Atlantic.*

ICSEAF - Catches increased from 36.300t in 1986 to 44.000t in 1988. This was reduced to 35.800t in 1989. In 1989 catches in ICSEAF fishing grounds for the Portuguese fleet were, 17.800t for hake, 8.274t of other species, totaling 26.154t. However, Namibia appeared for the first time with a catch of 24.585t, South Africa had catches of 1.569t, Falklands 9.676t, totaling 35.830t.

Total catches for all fishing grounds, declined from 404.300t in 1988 to 331.007t in 1989 catches of fish have declined in all fishing grounds, but particularly in National Waters, see TABLE III.

Landings of Processed and Production of Fresh, Frozen, Smoked, Canned, Fish Meal and Fish Oil Industries.

Table 4 indicates the production of landings of fish since 1966-1989, and also processed fish.

Frozen fish industry grew from 361t in 1965 to 63.000t in 1986, declining to 50.299.10t in 1989. National production of canned fish increased from 42.789t in 1987 to 50.745t in 1989. For production of canned frozen and salted fish in the period of 1987 - 1989 we have a total of 114.500.9t in 1987 increasing to 112.665t in 1989.In addition to manufactured fishing industry, the Portuguese Fleet is also processing fish on board in the coastal fleet. Production of 51.2 tons from

the coast of Portugal and 37.801t from the North Atlantic ; 7.214t from Halvinas, which is a new fishing ground for the fleet, that has to look for new sources of fish, supplies, due to the closing of the Canadian fishing grounds, by the establishment of 200 mile limit.

This is a very vertically integrated industry, as the majority of the large industrial processors are also the fleet seiners and have their own companies for frozen and fresh fish production, export and import and drying units for cod.

This also shows the specialization by auction markets for certain species, e.g. Matozinhos - "sardines, Sesimbra -"black secabard fish" ; Olhao - "hake". It has not been possible to include the statistics for 1990 & 1991 as they are not reportedly available from the Gabinete Estudos e Planeamento das Pescas or their supplying source, which are prohibited from supplying those statistics.

The statistics available for 1989 refers to landings in tonnage and average values for Matozinhos, Peniche, Lisbon (DOCAPESCA), Sesimbra, Olhao.

Matozinhos with 34.485.8t for sardines the leading species at an average value of Esc. 42.60 $ compares to Peniche with 18.150.8t, at an average value of Esc. 47.30 $. Matozinhos is also the leading trade centre for horse mackerel 7.073.4t at an average value Esc. 210.40 $ ; Peniche with 5.169.0t at an average value of Esc.188.30 $ ; 251.40 $ /kg and landings of 1.537.8t in Sesimbra. Sesimbra is also the leading centre for black secabard, with Madeira.

As for hake, Olhao had a leading position of 1.354.3t at an average value of Esc.826.90 $, which was also the highest price paid in these 5 leading fishing markets.

*Price Spreads and Differentials Between Fishermen and Consumers.*

Price spreads between producers or fishermen are very high for many species as can be seen from TABLE VI, for the period 1987 to 1989. The main price spreads are for horse mackerel, national and imported, seabream, secabard, and also imported hake. This table indicates spreads or differences of prices between the producer or importers on one side, and consumers on the other, from 1987 to 1989. Horse mackerel has a price in the producer of Esc 140.60 $ and a price to the consumer of Esc 326.40 $. In 1989 price in the producers increased to Esc 164.80 $ and to the consumer Esc 362.90 $.

These high price spreads are due to intensive concentration in this industry, particularly in fresh, frozen, refrigerated and canned sectors. As will be shown in another study on the International Monopolistic Aspects of World Trade of Fishing Industries in Portugal, which will also be presented at this VI IIFET Conference. However, TABLE VI will indicate, price differentiations by types and categories of cod fish for 1989 and 1990.

*Price Differentiations by Qualities, Categories, Geographic Locations and Types of Craft (Fishing gear).*

There is also differentiating price by geography locations of landings, regions, by qualities, and categories vary for trawler, polivalente and cerco, as shown in statistics below. Prices vary for horse mackerel, TABLE VIII.

Price differentiation is also for hake, for trawler polivalente and cerco. There are differentials in prices by categories qualities of fish (cod) and price differentiation by typing of craft and regions for horse mackerel and hake, as follows.

*Price Differentiations of cod by Quality and Category.*

Prices of codfish varies by types and categories of fish which different as follows[1] :

| | 1989 | 1990 |
|---|---|---|
| 1. Special | 1.105,00 $ | 1.320,00 $ |
| 2. Matured | 1.000,00 $ | 1.230,00 $ |
| 3. Grown | 870,00 $ | 1.020,00 $ |
| 4. Corrent | 720,00 $ | 795,00 $ |
| 5. Small | 577,00 $ | 625,00 $ |
| 6. Big assorted | 520,00 $ | 560,00 $ |

In addition to this difference there is differentiation by type of craft and regions, as follows for 1989, as related to hake and horse mackerel in table 7.

Price differentiation also varied by fishing grounds or countries of origin. Price of hake from South Africa is higher than from Chile of Argentina. Price of cod from Iceland and Norway is more expensive than Canada or Spain.

## 3. CONCLUSIONS

1. Production of fish catches and landings have been declining strongly since 1963 to the present time, particularly landings from continental Portugal and Madeira Islands, and Azores.

2. This has led to strong imports of fresh and frozen fish and also processed fish on board, which has been an important innovation.

3. Price of fish by species has increased strongly in the producers or fishermen, but much less, than the increase in price to the consumers. In many cases this difference or spread, of fish prices, has been 300 % to 650 %. Due not only to the shortage of fish but also to the large price spreads between producer and consumer, fixed by monopolistic groups in the form of oligopolies and oligopsonies, which have replaced the former totalitarian government monopolies and corporative guilds.

Because the Portuguese government has refused to take action and also to undertake the necessary scientific studies. On the other hand, the Directorate general of Competition of EEC also refused to study this problem and take action according to their letter of 20/4071991 ref 0037321.

4. the Portuguese government has refused also to supply updates statistics on landings, prices, processing, imports and exports and aslo the heavy concentration of quantities and prices of species purchased in the main wholesale auction markets in Portugal. they allege that they have to protect individual firms. In so doing they are not really protecting the numerous small firms operating in the market under free competition under EEC regulations. In fact, they are really shielding the large and the influential, which are operating as trusts or oligopsonies and monopsonies in the market of fresh, frozen, canned and codfish. In exchange for this protection, these firms are reportedly major contributors to the main Portuguese political parties.

5. There are no statistics available since 1989 from Gabinete, a Estudos e Planeamento das pescas. In denying these statistics and blocking scientific research in the economics of fisheries, the Portuguese government, is impeding the realistic knowledge of fisheries in Portugal today.

6. These depth studies are also justified to verify to what extent those firms are responsible for the rise of prices to consumer, contributing also to the rise of inflation.

7. Moreover, the Directorate General of Prices and Competition of Portugal has not studied high prices spreads of fish caused by abuse of economic power in form of oligopolies and monopsonies.

1. Data from CRCB.

8. Also.Direcçäo Geral de Inspecçäo.Economica, Inspection of Supervision for Economic Activity, has also refused to study of high price spreads of fish, alleging they cannot intervene or interfere because of the rules of the EEC guaranteeing free competition, according to their letter of July 15th, 1991 ref 004425. They both confuse free competition with freedom to monopolise and speculate.

9. The monopolist aspects of fish monopolies in Portugal will be treated in a separate paper, also presented in this VI IIFET Conference.

10. We may conclude that there has been a decline in landed fish in Portugal with an increase in price. The decline of supply can be due to the depletion of stocks, but it can also be bcause of the influence of monopolistic practices. It is a well known fact that the existence of monopolies in fishing leads to the depletion of stocks.

11. Although the Portuguese Government claims to have invested over 50 million contos(£12.5 million) for the renewal of the fleet, only large vessel owners also operating processing units for frozen fish and drying cod, and also wholesalers operating as oligopsonies under vertical integration, they have been the main bonifarctors. Consumers ans small fishermen interests have been jeopardize. Moreover, the Government did not undertake economic studies, for planning and justify such investments to benefit the consumer, and the small fishermen.

There has been a recent ministerial reform extinguishing Gabinete das Estudos e Planeamento das Pescas, IPCP Instituto Portugues de Conservas Ipescado, Inspecçäo Geral das Pescas, and Instituto Investigaçäo das Pescas, alleging too many people which absorb 2/3rds of the budget, the point is that none of these organizations undertook the necessary research required for the development of fisheries.

**TABLE I**
**CATCHES AND LANDINGS IN CONTINENTAL PORTUGAL 1965, 1979, 1985 AND 1989. MAJOR LANDINGS OF SPECIES IN TONS**

| SPECIES | 1965 | 1979 | 1985 | 1989 |

# Monopolistic Aspects of Word Trade of Fishing Industries in Portugal

**Salviano Cruz**

Estudos Económica Sociais. Rua Duque De Palmela, 27, 4°E 1200 Lisboa, Portugal

ABSTRACT

*Concepts of free competition, monopolies, oligopolies, monopsonies in international trade are described for the portuguese markets. From a large producer-exporting country of fish, Portugal has been declining in production of fish. As a result, Portugal has increased the imports of fish. Portugal's import/export markets are controlled by foreign companies, particularly for cod, hake, redfish, etc. Portuguese companies also operate as oligopolies/oligopsonies particularly in the auction markets and export trade with product differentiation in large scale export market and monopolistic control through restrictions and denial of statistical data.*

## 1. INTRODUCTION

Present studies of fishing industries, seem to ignore the important differences of structure and price differences, "price spreads" between producers (fishermen) and consumers in Portugal and in other countries.

It is even more strange that the influence of dominant firms, operating as oligopolies, oligopsonies, and monopsonies, price differentiation and other forms of monopolistic competition and imperfect competition, is ignored by economists.

## 2. CONCEPTS OF FREE COMPETITION, MONOPOLIES, OLIGOPOLIES, AND MONOPSONIES IN INTERNATIONAL TRADE.

Definitely, although there is free access to auction markets, there is not free competition in the fish trade industries in Portugal. Table 1 indicates prices to producers (fishermen) and consumer and its relationship to production landings[1], for 29 species, including the most important ones,

1. This table is based on the authors study on Institutional Factors of Marketing and Distribution in the Fishing Industries Under Monopolistic Competition in Portugal (1990) ; for the NATO Advanced Scientific Research Workshop in Econometric Modelling in World Trade in Groundfish, held at Memorial University of Newfoundland, Canada, Aug. 14-18th 1989.

| | | |
|---|---|---|
| sardine, | horse mackerel, | mackerel, |
| hake, | secabard white, | faneca, |
| octopus, | secabard black | congres, |
| spanish mackerel, | squid, | lobster, |
| common sea bream, etc. | | |

The table reveals prices in the producer and consumer for the years 1967, 1973, 1979, 1985 and 1989. In this year it also studied prices in Lisbon and Porto only, and not for the total country.

These statistics also indicate price spreads from producers to consumers for each of these species and the relationship between these prices and production, (landings).

The difference on "spreads" in price indicate a situation synthomatic of monopolistic competition. Also table 2 on evolution of prices of imported frozen hake in 1987 and December 1988 in Lisbon and Porto and in the country and also regular prices for hake from January to December in 1988. The maximum point for consumers in Lisbon was Esc.566.3 in December 1988. The maximum price for Porto was Esc.565.3 in November 1988.

Although, there are really many sellers and many buyers for fish in the auction markets, there is no indication of free competition, as buyers and sellers have very little to say on market conditions, as trade is controlled by small powerful groups of buyers and sellers, oligopolies or oligopsonies, which operate under monopolistic competition on imperfect competition, and not under free competition.

Figure 1 discuses free competition with lines SS' indicating supply and DD' the meeting at point C to show the equilibrium price for quantity OQ and price OP. PCD is the area of surplus of consumer, the area OPCSOQ, indicates surplus of producers. This only occurs when there are many suppliers of fish and many buyers.

Monopolistic competition on oligopoly, oligopsony, as it is happening in fresh fish,frozen fish, export, import markets, cod imports, and buying in bulk directly from vessels as it is the situation for the Northwestern Atlantic Fleet and C.R.C.B. (Companhia de Refrigerados e Comercio de Bacalhau). This company and vessel owners are operating under bilateral monopoly or oligopsony, both are bargaining outside the auction markets, by vertical and reciprocal proposals, purchasing fish in bulk for the whole boat supply.

### *2.1 Buying Fish Under Monopsony and Oligopsony and Free Competition*

Figures 3 and 4, will indicate the direct relationship of price spread between the fishermen, wholesalers and consumers illustrated by table I for price between the fishermen and the consumers.

Wholesaler in figure 3 will purchase only quantity OC, at price CH under monopsony, at price AP not quantity O, as indicatedfor free competition. He will pay only to fishermen price CH monopsony price for quantity OC while price to consumer will be CS under monopsony (monopoly of the buyer), and not price AP for quantity OA under free competition.

Figure 4 indicates the spread of prices of fish sold in auction market and prices paid by the consumers, as shown in table I for sales of species from fishermen to the consumer, and also for table 2 indicating the relationship of prices paid by the important frozen hake from Chile, Argentina and South Africa and price paid by consumers in the continent of Portugal and Lisbon and Porto, in December 1987 and in several months from january through December of 1988.

The final price paid by consumer is theoretically fixed at point, where curve NA'C'meet AI POINT P' under figure 4 aggregate supply or aggregate cost all the cost involved between the fishermen and the consumer, meet the curve AGR at point P' for price to the consumer AP' under monopsony, and not, at free competition price OP for quantity OQ' larger than quantity OA at price AP under monopsony.

This explains the large price that Portuguese consumers are paying at retail market for fish. For example, sardines selling at one of the leading Supermarkets, retail sardine price between Esc.600-750 /kg, which auction market wholesalers were purchasing between Esc.100$00 and Esc.200$00/kg.

There is a company, Tavamar, which has the monopoly of importation of chilean frozen hake. How much the fishermen will receive for this consumers price ?. Refering to figure D AP', the answer depends on several relationships, between the final demand for the consumer AGR aggregate revenue curve for fish and the average revenue curve on aggregate cost and DAR for aggregate cost for processed fish sold to consumer. This will depend on the degree of elasticity of demand for fish sold by fishermen in the auction market and the elasticity of demand processed fish sold to the ultimate consumer, which it is not known.

*2.2 Fresh Fish, Dominant Firms in the Fishing Trade.*

We have divided the dominant firms by sectors. Under the sector of fresh fish, there are the following dominant firms :

i) Frescal with 22 % of fish, is the leader of fresh sector market

ii) A group with Coimbra cia 6 %, Tavamar, Central Atlantico, Manuel Carvalho, Paceco, F. Martins, Eurotejo, Tavamar.

Figure 5 indicates the flow of fresh fish from the producers to the consumer with main firms interfering in the flow, from the importer, or the fishermen in the auction market to the consumer. There are about 25 firms for all sectors under oligopolies, oligopsonies, monopolies, bilateral monopoly as follows :

- Fresh Fish
- Frozen Fish
- Processed Fish
- Exported Frozen Fish and Imports
- Imports of salt fish and cod fish
- Fish canning industry
- Coastal & long range fleet
- Cod monopolies
- Bilateral monopoly buying in bulk from vessels and not, through auction markets.

In table 4 the evolution of prices from 1984 to 1989 is indicated by species. This shows the large increase of prices by species and also the categories of fish by prices variation.

*2.3 Dominant Firms for Frozen and Salt Fish Industry.*

Although there is a pseudo free competition in auction markets for fish there is restriction into entrance. Moreover, there is the drop in price by competitive bidding of small buyers, so that large dealers may enter the market and force prices even lower.

Therefore in the buyer side in Portugal auction market there are symptoms of real practice of monopolistic competition, oligopsony. From the fisherman producer side there is practice of oligopolistic control as there is also large concentration of landings by a group of 15 out of 120 vessels which landed 40.8 % of fish of this craft for the period from 1979 to 1986 as presented in figure 5. From the buyer side for fresh and frozen fish, there is a small group of buyers that control a large majority of fresh and frozen, processing, and salted fish. These dominant companies are :

1. Coimbra Company.
2. Beirafrio.
3. Eurotejo.
4. Frescal.
5. CRCB.
6. Paceco.
7. Tavamar.
8. Central Atlantics.
9. Manuel Carvalho in Aveiro and Matozinhos.
10. Tavares Marcarenhas.

11. F. Martins.
12. Machado o Cardoso Aveiro and Lisbon cod imports.
13. RAR.

These companies operate not only in Lisbon (Doca Pesca), but also throughout the country through branches.

Coimbra and company hold branches in Viana do Castelo, Aveiro, Figueira do Foz, Nazar, Lisbon, Doca Pesca, Sesimbra, Olho, and Portimo. Moreover, Coimbra & Co owns 60 % of Beira Frio which in itself claims to have over 40 % of frozen fish trade. Coimbra constitutes a holding company for the fresh, frozen, processing, and catch of fish, through leasing of 5 fishing boats operating in northwest atlantic fleet.

Coimbra and Beira Frio constitutes holding companies for fresh, frozen, processed, and exports. Imports internal market and monopolistic control of exports and buying.

Coimbra and other dependant companies, have 60 % of their businesses in frozen fish, 40 % in the fresh fish market. They control the import and export trade market of frozen fish, holding 15 % of trade. Some these companies operate in inter partnership basis. Eurotejo is practically owned by Manuel Carvalho & Co. Eurotejo also owns a significant share in Manuel Carvalho & Co. Coimbra imports and sales of cod corresponds to 4 % to 6 % of fresh fish, represents 3 % of frozen fish, 4 % exports and 15.2 % of exports of frozen fish. The price structure for Coimbra from producer or importer is outlined in figure 6 :

Four companies (CEE, Grupagel, Fropesca, CRCB) controls 80 % of the frozen fish industry : Coimbra and Beira Frio claim to hold 40 % of frozen fish market.

Coimbra also states that it is almost impossible to import a single container of frozen hake from Chile, due to the iinternational monopolies which practice the abuse of economic power. Tavamar has the monopoly of frozen hake from Chile as noted before.

### *2.4 Vertical Integration of Frozen Fish.*

In frozen fish industry there is a high integration with fishing fleet due to large companies with freezing equipment on board. Most of these fishing companies also extended their activities to processing and selling of final product. They have also purchased vessels to meet the expanding demand for other frozen products. Table V Landings of Processed Fish on Board Vessels of the National Fleet in 1989 ; see table 6 on Import and Export of Fresh, Frozen, Fillets and Canned Fish 1986-1989.

In cod salting industry vertical integration is even more intensive. After salt ships, there are inland salting and drying places. They also fill out their excess capacity with imported green cod, see table VI Imports of Cod. They all possess their own processing and drying installations. The two most important companies produce over 5000 tons, each corresponding to more than 25 % of the market

In the fish canning industry there is no integration for raw materials fish, but there integration for processing cans.

In table 5 we have the production of all processed fish in Portugal in period 1987-89, which indicates a total of 114,500.9t in 1987 and 112,665 tons in 1989. Canned Fish increased from 42,789 tons in 1987 to 50,745.0 tons in 1989. The main production was sardines increasing from 26,171.7 tons in 1987 to 29,522 tons in 1989. Tuna also increased from 10,349.2 tons in 1987 to 13,980. Mackerel increased from 3,647.4 tons to 9,136. in 1989.

Fish canning is highly concentrated, COFACO controls 51 % of production of sardines and also tuna which is localized mainly in the Azores. Other important leading companies are also Vasco de Gama with 20 %, Serrano 10 % Ramirez 10 %. The distribution is concentrated in one company, CORESA with 51 %.

Frozen Fish had a production of 59,099.0t in 1987 and 50,299t in 1989. The main production was hake 17,060.00 in 1987 and 6,008 in 1989, red fish declined from 23,960t in 1987 to 11,812t in 1985.

Friopesca is a holding company for 17 companies indicated in table VI ; firms operating in vertical integration for fish processing marketing and distribution of frozen fish for internal and export markets. These companies dominate the fishing trade of Portugal. Most of these companies are also interconnected. and are also importers and exporters of fish.

The most important vessel owner companies also control fish exports and importing fish industries ; through frozen fish industries, Empresa de Pesca de Aveiro exported 406.000 contos of frozen fish in 1988 and a total volume of business 44.157 thousand contos. Sociedade de Pesca Miradouro the leader of FrioPesca a holding companies for exporting frozen fish also had sales of in 1.960.9 contos and also other vertical integration companies are indicated in table VI :

*2.5 Absorption of State Monopolies by Private Companies.*

According to recent legislation, the Portuguese government appearing to obey rules for "free" operation competition of EEC extinguished Comisso Regulidade do Comercio do Bacalhau CRCB, which controlled the landings and distribution of commerce of cod in Portugal and also the frozen fish trade operating as a monopsony, controlling the buying, landing and supply of the cod and also the frozen fish trade. Although against the EEC legislation the Government of Portugal, left in operation those 17 dominating vertical intergration companies operating as oligopolies and oligopsonies.

## 3. CONCLUSIONS

(i) Although there are over 19 auction wholesale fish markets in Portugal, there is no free competition, because small dealers and small fishermen cannot influence the buying and selling as the markets despite the fact that both groups may bid for fish.

(ii) Large wholesalers or manufacturers operating in various sectors, fresh fish, frozen fish, processed fish, exporting and importing and also cod fish importing or importingand canning industries a few of which operate as dominant firms controlling the market as oligopolies, monopolies, oligopsonies, monopolies or monopsonies and influencing prices.

(iii) "Armadores", or owners of trawlers also operate as controlling groups in vertical integration. In coastal fleet 15 vessels out of 120 control 40.8 % of landings which represents almost 51 % of the fish presented in auction markets during the period 1979-1986.

(iv) Price spreads between fishermen and consumers have varied from 200 % to 650 % or more.

(v) Abuse of economic power and monopsonies are recognised but no corrective steps are taken by authorities which confuse free competition with freedom to monopolise.

(vi) Portuguese authorities protect monopolies, by encouraging big business and abuse of economic power, even when it means violation of articles 85' and 86', refusing also to intervene in recognising situations of economic power jeopodising the interests of the consumer

(vii) International authorities like CEE.do not recognize the necessity of studying the abuse of economic power and violations of articles 85' and 86' of the Treaty of Rome by fishing firms in Portugal, as revealed by the letter of the Directorate General of Competition of 20/10/1991 Ref. 0037321. This has also beenfollowed by Directorate General of Prices and Competition of Portugal, and Dirreco Geral de Inspeco Economica. Inspection of economic activities according to the letter of July 15th 1991 Ref. 004425. They confirm the legislation of CEE. for free competition with abuse of economic power.

(viii) Government refuse to support economic scientific research and participation of Portuguese scholars on international meeting and advanced seminars. They prefer to accept religious bias pressure groups like Opus Day instead of studies.

# Markets and prices
# by
# Frederic LANTZ and Martine ANTONA

La formation des prix des produits de la pêche fait l'objet de nombreuses études qui mettent en évidence la disparité et la variabilité des prix comme résultante des conditions d'offre et de demande. Les pêcheries sont confrontées à des problèmes d'adéquation entre une offre instantanée sujette à de fortes fluctuations et des capacités d'absorption du marché souvent peu flexibles. Cette offre aléatoire, peu dépendante à court terme de l'évolution des prix, caractérise les marchés des produits de la mer. Elle est en revanche fortement dépendante de facteurs environnementaux et biologiques qui jouent sur la taille, la disponibilité et l'accessibilité du stock. La question du mode de formation des prix a donc été intégrée à l'analyse globale des pêcheries pour étudier les conséquences du fonctionnement et/ ou de l'évolution des marchés sur l'exploitation des ressources.

Cette session présente différentes approches de ces questions. Quelques communications abordent la modélisation du marché d'un produit particulier en s'attachant aux spécifications des fonctions d'offre et de demande (Ioannidis, Wright & Copes). D'autres sont consacrées à la modélisation de la formation des prix sur les marchés au débarquement. Les contributions portent en particulier sur l'influence des conditions spécifiques de chaque transaction - nature de la ressource, type de vente...- sur la détermination des prix (Kirman, Ty & Gates). Ces analyses amènent à s'interroger sur la signification du prix qui est fixé lors de l'échange et sur l'agrégation qui peut être envisagée, tant au niveau des paramètres de l'offre (facteurs qualitatifs liés au poisson, taille, type de pêche, origine...) qu'au niveau des prix. Enfin, plusieurs communications s'attachent à caractériser la nature et les conditions de l'offre et de la demande de produits de la mer, sans recours à la modélisation.

Les récents travaux dans le domaine de l'analyse des prix et des marchés montrent qu'il convient, en particu-

The formation of fish price has been the object of many research studies. They have revealed the disparity and variability of prices resulting from conditions of supply and demand. The fisheries are faced with adequation problems between an instantaneous, strongly fluctuating supply, and markets with a frequently inflexible capacity to absorb the products. This uncertain supply, relatively independent of prices in the short term, is typical of fishproducts. On the other hand, this supply is very dependent on environmental and biological factors influencing the size, availability and accessibility of the stock. The question of how prices are determined has therefore been integrated into the overall analysis of fisheries in order to study the influence of market fuctioning and /or evolution on resource exploitation.

This session will present different approaches to these questions. Two communications will deal with modelling markets of a particular product, concentrating on the specifications of its supply and demand functions (Ioannidis, Wright and Copes). Others are devoted to modeling the formation of prices on landing markets. They are particularly concerned with the impact of the specific conditions of each transaction - nature of the resource, type of sale - on price setting (Kirman, Ty and Gates). These analyses lead to questions about the significance of the price established during the transaction ; the formulation of aggregates concerning supply parameters (qualitative factors linked to type and size of fish, fishing technique, catch location...), as well as prices. And finally, several communications will not adopt a modeling approach. Their goal is to describe the nature and conditions of supply and demand of fishproducts, particularly in Iceland and Japan.

Recent work in the area of price and market analysis has shown that it is preferable to proceed on a disaggregate level, particularly in modeling. This approach takes into

lier dans le cadre d'une modélisation, de conserver une désagrégation fine pour prendre en compte la diversité des prix et leurs interaction. En effet, l'utilisation d'un prix unique associé à une espèce, ou encore le recours à un agent représentatif pour caractériser les comportements sur un marché sont le plus souvent inapproppriés. Plusieurs analyses allant dans ce sens sont présentées dans cette session (Kirman, Ioannidis). Il faut souligner que ces travaux ont pu être réalisés grâce à l'essor de moyens de calcul permettant de stocker et de traiter l'information.

Dans sa communication, A. Kirman présente ainsi une modélisation d' un marché au débarquement sur la base de données individuelles de transactions gré à gré. L'analyse empirique des données recueillies revèle l'absence de convergence vers un prix d'équilibre mais montre en revanche une distribution des prix qui apparaît stable dans le temps. Des comportements individuels d'achat et de vente sont spécifiés, d'où un second résultat intéressant : les propriétés standards de la fonction de demande qui n'apparaissent pas au niveau individuel, sont en revanche observables lorsque l'on traite les données agrégées. En conclusion, l'auteur souligne que la structure et l'organisation du marché déterminent la nature de l'équilibre réalisé, ouvrant ainsi des perspectives de recherche dans l'analyse de différentes structures de marché (marchés aux enchères, marchés contractuels...)

N. Ty et J. Gates s'interrogent sur l'influence de la nature de l'offre sur la formation des prix au débarquement du cabillaud, dans le cas d'un marché d'enchères. Ils effectuent une régression en terme de prix hédonistes, sur la base de données de transactions individuelles. Les facteurs qualitatifs testés sont d'une part, ceux relatifs au produit lui-même, d'autre part ceux relatifs au marché.

Un second groupe de communications apparaît plus centré sur la question de la spécification des fonctions d'offre et de demande. Ainsi, pour C. Ioannidis, considérer un prix moyen pour établir un système de prix de retrait peut être source d'une allocation sous-optimale. L'illustration en est fournie par les marchés français du cabillaud et de l'églefin qui se caractérisent semblablement par une demande sensible à la taille du produit. La prise en compte de la variabilité due à la nature de la demande permet alors de limiter le coût budgétaire de mesures de stabilisation du prix, du type prix de retrait. La communication de C. Wright et P. Copes aborde la question de la spécification de la fonction d'offre pour le marché du saumon aux USA. Les auteurs s'intéressent à la relation de long terme qui résulte de la compétition entre deux segments d'offre (offre de pêche et d'élevage) confrontés à une seule demande. Ils en déduisent les

account the diversity of prices and of their interactions. Use of a single price for a species, or characterizing market behavior with a representative agent, is usually inappropriate. Several analyses on these lines will be presented in this session (Kirman, Ioannidis). It should be noted that these works could not have been carried out without the rapid development of means of calculation enabling information to be stored and processed.

Thus, A. Kirman presents a landing market modeling on the basis of individual data about mutual agreement transactions. Empirical analysis of collected data does not show convergences toward an equilibrium price but rather a range of prices which appear to be stable over a period of time. Individual buying and selling behavior is specified, leading to a second interesting result : the standard characteristics of the demand function do not appear on an individual level but are observable when the aggregate data is treated. In conclusion, the author emphasizes that market structure and organisation play a determining role in the equilibrium established. This opens perspectives of research in the analysis of different market strutures (auctions, contractual markets...)

N. Ty and J. Gates focus on the influence of the type of supply on the formation of landing prices for cod in an auction context. They formulate an hedonic price function as a regression of the observed price of cod against its qualty attributes, on the basis of individual transaction data. The qualitative factors tested are the factors relative to the product itself, and those relative to the market.

A second group of communications are more centered on the question of the specification of supply and demand functions. For instance, for C. Ionnadis, using an average price to establish a withdrawal price system can result in a sub-optimal allocation. This is illustrated by the French cod and haddock markets which are characterized both by a demand influenced by product size. Taking into account variability due to the nature of the demand can therefore reduce the budget cost of price stabilization measures, such as withdrawal price scheme. The communication of C. Wright and P. Copes raises the question of the specification of the supply function for the salmon market in the USA. The authors are interested in the long-term relationship resulting from competition between two supply segments (fishing and farm supply) confronted with a sole demand. They deduce from this, the potential consequences on the activity of the two sectors. O. Klemenson and G. Bourgignon emphasize the role of imports and exports. O. Klemenson describes the impact of export incentive measures on price variability in Iceland and the consequences for the fisheries. G. Bourgignon makes an analytic description of the role of imports and exports in the supply and demand of Japanese seaproducts.

conséquences potentielles sur l'activité de chacun des deux secteurs. O. Klemenson et G. Bourguigon mettent l'accent sur le rôle des importations et des exportations. O. Klemenson décrit l'impact de mesures d'incitations à l'exportation sur la variabilité des prix en Islande et leurs conséquences sur les pêcheries. G. Bourguigon effectue une analyse descriptive du rôle des importations et des exportations sur l'offre et la demande de produits de la mer au Japon.

Trois communications fournissent une analyse détaillée des structures d'organisation de l'offre et du marché des produits de la mer au Japon. Ainsi, K. Miki et T. Yamamoto présentent le rôle du système de stockage pour la stabilisation des prix. N. Odaka et T. Yamamoto montrent l'importance du réseau de coopératives de pêche y compris dans la mise en marché. Le système très complet de statistiques des pêches fait l'objet de la communication de T. Yamamoto, qui souligne son intérêt pour le suivi économique et social des activités artisanales et industrielles.

Les perspectives qui s'ouvrent dans le domaine de l'étude des marchés et de la formation des prix sont multiples ; d'une part, les aspects séquentiels relatifs aux marchés - séquences de vente, nature périssable du poisson- et leurs implications sur la dynamique de l'exploitation des pêches peuvent être traités sous la forme de problèmes dynamiques dans le cadre des développements de la théorie des jeux. D'autre part, les méthodes d'analyse économétriques liées à la théorie de la cointégration permettent d'aborder au travers de tests statistiques les questions relatives aux relations d'équilibre et de dépendance entre les prix et les marchés, qu'il s'agissent de tendances communes d'évolution des prix de certains produits ou encore de relations entre prix d'un même bien sur différents marchés.

Three communications make a detailed analysis of organizational structures of the Japanese fishmarket. K. Miki and T. Yamamoto present the role of storage systems in price stabilization ; N. Okada and T. Yamamoto show the importance of the fishing cooperative network, all the way to the market stage. The very complete system of fishing statistics is the subject of the communication of T. Yamamoto, who underlines its usefulness for economic study and social supervision of artisanal and industrial activities.

Multiple perspectives are being opened in the area of market and price formation study :

on one hand, the sequential aspects relative to markets - sales sequences, the perishable nature of fish - and their implications for the dynamics of fish exploitation can be treated in the form of dynamic problems in the framework of game theory development ;

on the other hand, methods of econometric analysis linked to the cointegration theory make it possible to study, through statistical tests, questions concerning the relations of equilibrium and dependence between prices and markets, whether they be common tendencies in price evolution of certain products or relations between prices of the same product on different markets.

# Market Structure and Prices : the Marseille Fish Market

**Alan Kirman** *

European University Institute, Department of Economics, via dei Rocettini 9, Badia Fiesolana, 50016 San Domenico de Fiesole, Fi, Italy

ABSTRACT

*The purpose of this paper is to give a brief account of some recent work at the micro level on the formation of fish prices. What has become clear is that the behaviour of the individuals on the particular market that we have studied, the wholesale fish market in Marseille, is rather complicated and does not correspond to the classical description of actors in a competitive market even though there are many buyers and sellers. Indeed the purchases and sales at the individual level often bear little resemblance to standard demand and supply functions. In the aggregate, however, standard properties, in particular that of downward sloping demand, do reemerge. This leads to two conclusions which are important in studying such markets. Firstly, the "good behaviour" at the aggregate level should not be thought of as resulting from the underlying actions of well behaved individual participants, but rather as emerging from the procedure of aggregation itself. Secondly it would be a mistake to try to base predictions as to the consequences of a change in the economic environment on the reactions of a single "representative agent". Furthermore an examination of the market does reveal interesting patterns in behaviour which are of interest in themselves when trying to explain market outcomes.*

## 1. INTRODUCTION

The fish market has a long tradition in the economic literature. It was the subject of a debate between John Stuart Mill [1869] and Thornton [1869, 1870]. The subject of this discussion was the nature of the prices charged for the same type of fish during auctions. The two points of view were firstly that there were either multiple equilibria or no equilibrium

* I owe a special debt to Annick Vignes with whom I started this work and who spent many cold, very early mornings at the Marseille fish market She obtained the raw data from the market authorities and a first analysis may be found in Kirman and Vignes [1990]. I am also indebted to Mary McCarthy, Wolfgang Härdle, Jean-Pierre Malrieu, Nick Vriend, and Gilles Teyssière for their collaboration. Lastly I would like to thank Paul Klemperer who asked several pertinent questions, some of the answers to which are given here.

prices, and secondly, that these were out of equilibrium or disequilibrium prices. This debate was reopened by Negishi [1986] and was followed by a discussion by Ekeland and Thommesen [1989] and a reply by Negishi [1990]. The central issue of this debate was how one should interpret the notion of equilibrium on a market such as that for fish.

One of the reasons for the interest of economists in the fish market is that successive days are separated since the product is perishable. It was this that led Pareto and Marshall's followers [1] to use it as an example. Such a market can be considered, with some reservations, as one in which, in each period, stocks are fixed and prices are used as the strategic variable.

In the particular market analysed 574 buyers and 37 sellers come together each day and transact 129 types of fish. Prices are not posted and all transactions are pairwise. There is no auction mechanism unlike the Thornton examples, and unlike many of the major fish markets. Given the numbers of agents involved in the same place at the same time one might be led to expect that, at any moment, the same type of fish would be sold at essentially the same price. This, as we will see, is far from being the case. Furthermore, one could expect to see evidence of the standard assertion that as the day progresses, prices diminish. This is again not true. What is needed first is a general analytical framework which would permit the sort of price dispersion and evolution of prices over time that one actually observes. Such a framework clearly is not competitive in the standard sense. At no point in time is there an "equilibrium price" which clears the market. Nor, however, is there convergence to such a price after trading at "disequilibrium prices". Thus neither Walrasian nor Edgeworth type analysis is applicable to this sort of market. Rather, the market should be thought of as a game in which individuals have strategies consisting, for sellers, of prices to charge at each point in time, or for buyers, of demand functions at each round which will depend on the history of the market up to that point. Thus after a series of meetings between buyers and sellers and a number of transactions each individual decides on what to charge for the remaining stocks, or what to demand at any given price. The nature of the equilibrium will depend on the information possessed by the individuals. Buyers may or may not know sellers' characteristics and vice versa. Individuals may or may not know what transactions have taken place and what initial stocks were held on the market. All of these factors will enter into the information sets which condition the strategy. How complete information is will determine the characteristics of equilibrium prices. Equilibrium price distributions in this sense, will then be different from those described by Diamond [1987] and Butters [1977] for example. The fact that there is price dispersion may in part be due to lack of information and the cost of obtaining that information but may also be due to price discrimination by sellers who know the demand of the buyers they face. Buyers may choose to search over sellers or to purchase from some limited subset. As we will see, both types of behaviour are apparent in the market. However, close examination of the data shows that the separation between "loyal" and "searching" buyers is not as clear cut as it might seem.

All of these phenomena should be captured by the theoretical model. I shall give a very general framework which will allow the specification of strategies based on particular levels of information at each point in time. This model is sufficiently general to allow, as possible outcomes the phenomena actually observed. I shall then present an account of various analyses of the data which reveal certain features of market behaviour. The problem then remains, and it will be difficult to solve in full generality, of giving informational assumptions and optimising rules which will generate all these phenomena.

Our data are unusual in that they allow us to "follow" individual traders in the market. Hence, at each point we know who buys what from whom. We thus have a very clear picture of the evolution of the market over the day, although we do not have statistics on the initial stocks for each day : In fact, of course, we should treat the market as a dynamic game and recognise that the changes in stocks at the beginning of each day are, at least in part, endogenous and the result of the previous history of the market. However, if, as we shall see, the behaviour of the market is relatively stable over time then it is not unreasonable to think of the supply of fish as being largely dependent on factors exogenous to the market in question.

In a previous paper, Kirman and Vignes [1991], we examined the data for a single week. In Kirman and McCarthy [1990] we took a full month involving over 40,000 transactions and examined to what extent some of the price variability could be explained by "seasonality", i.e. the fact that the level of transactions varies considerably over the days of the week. We also tried to give explanations for some of the apparently asymmetric behaviour observed. In Kirman and Härdle

1. Hicks [1989] points out that Marshall himself, actually talked about the corn market whereas his successors used the fish market to eliminate the problems posed by the carrying over of inventories. More recently, Gorman [1959] in a well known unpublished paper and Barten and Bettendorf [1989] have analysed the demand system for the fish market.

[1993] we examined individual purchases over three months and found no simple classical monotone relation between prices and quantities. However, using non-parametric regression techniques we found such a relation at the aggregate level. Furthermore we found that, although there was no tendency towards a single equilibrium price for each type of fish the *distribution* of prices on the market was stable from month to month. Thus, however complicated the underlying game it is not illegitimate to think of it as being repeated over time.

This paper then presents a suggested analytical framework together with a number of salient empirical features of a fish market with a particular organization. The challenge for other economists is to specialise the framework by providing behavioural justification for strategies which yield equilibria with the characteristics revealed by the empirical data that we present. Some of the results described here provide indications as to some possible explanations but they are far from being complete. What is, however, already clear and has been emphasised by many authors[2] is that the structure and organisation of the market are of particular importance in determining the nature of the equilibrium realised. In particular the results in Härdle and Kirman [1993] showing that, at the aggregate level, the relation between prices and quantities purchased possesses the classical monotone declining property, is of interest. This reveals that simple aggregate properties may be the result of very complicated strategic behaviour at the individual level. It also shows that one should be wary of making any recommendations as to changes in market organisation based on the idea that the individual buyers in the market each have standard demand curves.

## 2. A SIMPLE MODEL

We consider the market for one perishable product with $m$ sellers and $n$ buyers[3]. The market evolves in a fixed number $T$ of rounds. Each seller $i$ has strategies which at each round $t$ specify a vector $x_{it} \in R_+^n$ of the prices which he will charge to each of the buyers. A strategy for each buyer $j$ specifies at each round $t$ a demand function $q_{jt}(p) : R_+ \to R_+$. In both cases the choice of the prices set and the demand functions will depend on two things : firstly, the strategies of the other players and, secondly, on who has met whom in the market. The model is then completed by specifying a matching process which, in keeping with the literature, will be supposed random. Thus a matching at time $t$ , a realisation of the random variable, will be a mapping $g$ from the integers $I = \{1, ..., n\}$ to the integers $I = \{1, ..., m\}$. A probability distribution must then be specified over the outcomes of the matching process for every time $t$. One might think, as an example, of each buyer as choosing a seller with uniform probability $\frac{1}{m}$, independently at each time $t$. A best strategy for a buyer i, then, will consist for each realisation of the matching process and for the associated price vectors of each seller i and demand functions of the other buyers $h \neq c$ of a demand function for each period $t$. Similarly for a seller it will consist of specifying the best price vectors for each matching and each period.

Thus to sum up, the model consists of :

1) A basic strategy set $B$ for buyers which is a subset of the product space of $Q$ where $Q$ is the set of functions $q : R_+ \to R_+$ satisfying

   i) every $q$ is continuous and monotone of economy

   ii) there exists a $\bar{p} > 0$ such that for every $q$ in $Q$ $q(p) = 0$ for all $p > \bar{p}$.

   Thus

   $B \subset \prod_T Q$ *i.e.,* $q \times q : \ldots Q$. Furthermore, we assume, $B$ is compact and convex.

2) A basic strategy set $S$ for sellers which is a compact convex subset of $R_+^{nT}$.

3) A matching process $M$ i.e.,

2. See, for example, Phlips [1988], Salop and Stiglitz [1982], Varian [1980].
3. In Kirman and Vignes [1991] we considered a continuum of buyers and sellers but this was to facilitate the technical problem later of establishing the continuity of strategies.

i) The mappings $f = (f_1, f_2, ..., f_t)$ where $f_t : I \to J$.

ii) A probability distribution over the finite set F of f.

4) A strategy $q$ for a buyer then associates with each $f$ an element of $Q$ i.e., $q : F \to B$ and $s$ for a seller associates with each element of $F$, an element of $S$ i.e., $s : F \to S$. The set of strategies for buyers is denoted $\tilde{Q}$ and for sellers $\tilde{S}$.

5) There is a continuous payoff function for each player $i$.

$$\prod_i (q_i \ldots q_n, \; s_{n+1} \ldots s_{n+m}) \quad i = 1, \ldots \ldots n + m..$$

6) The response function $\Gamma$ for each player is given for buyers by

$$\Gamma ; : \tilde{Q}^n \times \tilde{S}^m \to \tilde{Q} \text{ where } \Gamma_i = \underset{q}{Max} \prod_i (q_1 \ldots q_{i-1}, q, q_{i+1} \ldots q_n, s_{n+1}, s_{n+m})$$

and for sellers by

$$\Gamma ; : \tilde{Q}^n \times \tilde{S}^m \to \tilde{S} \text{ where } \Gamma_j = \underset{s}{Max} \prod_i (q_1 \ldots q_n, s_{n+1} \ldots s_{j-1}, s, s_{j+1}, \ldots s_{n+m})$$

We assume that for every $i$, $i = 1, ..., n$ and $j$, $j = n + 1, ..., n + m$, $\Gamma_i$ is continuous.

Denoting by $\tilde{Q}^n$ the $n$ product of $\tilde{Q}$ and by $\tilde{S}^m$ the $m$ product of $\tilde{S}$ then each $\Gamma$, $(\Gamma_1 \ldots \Gamma_{n+m})$ defines a mapping from $\tilde{Q}^n \times \tilde{Q}^m$ into itself. Given our assumptions a standard fixed point argument can be used to show the existence of an equilibrium.

The market can be envisaged as follows :

| | |
|---|---|
| Period 0 : | Initial stocks. |
| Period 1 : | Sellers specify prices. Buyers specify demands.<br>Matching takes place. Transactions take place. |
| Period 2 : | Given their information about what happened in period 1, sellers respecify prices, buyers respecify demands. Matching occurs. Exchanges follow. |
| Period T : | Last specifications by sellers and buyers, last matching and exchanges. |

All this does no more than give a formal framework which enables us to define the concept of an equilibrium. To characterise precisely the nature of an equilibrium requires that the $\Gamma_i$ be derived from maximising behaviour. For example, for a buyer would maximise his expected utility at each round $t$ given the known strategies of the other players and the matching up until $t$. The real difficulty here is *proving* the continuity of $\Gamma_i$ for the players. The difficulty of proving continuity is illustrated by Kormendi [1979] and Benabou [1988].

Without such a complete specification, however, our model would allow for extensive price dispersion (particularly since we have assumed that price discrimination is possible as each seller knows the buyers' characteristics), there will be no necessary tendency for prices to decline during the day as is commonly supposed and there is no a priori reason to assume that individual buyers will or will not search.

One important point to emphasise is that any strategy must be such that if the information set up to time $T$, is the same in two realisations, the next component of the strategy at time $t + 1$ should be the same. Thus it is important to specify what is known at each time. If, for instance, the individuals know initial stocks but only observe their own transaction strategies, they will be much more limited than if they observe everything that has occurred. Furthermore, it may well be the case that individuals choose to condition strategies on a limited part of the information they have available.

Although it is difficult to prove the continuity of strategies in a fully optimising context, it may well be the case that agents develop simple rules which are continuous. An interesting problem is the origin of such rules.

We now turn to a description of the data set and to an analysis of some of its features.

## 3. THE DATA

i) The market is open every day and there are 37 sellers and 574 buyers dealing in 129 types of fish. We have the following information for each transaction.

a) Name of seller
b) Name of buyer
c) Type of fish
d) Quantity sold (weight)
e) Unit price

Transactions are listed in chronological order for each seller.

### *3.1 Some Summary Statistics*

Of the 37 sellers one seller accounted for 15.5 % and 6 sellers shared 50 % of all transactions during the month. On the buyer side one buyer participated in 14 % of all transactions while all other buyers each recorded $\leq$ 1 % of the total volume of transactions. Ten of the 129 fish types were involved in just over half of all transactions. The average number of fish types traded by a seller in a day ranged from 1 to 32. Approximately 50 % of the sellers recorded average daily trading in 1 to 10 fish types over the three months analysed in Kirman and Härdle [1993].

As we observed in Kirman and Vignes [1991], the variation of prices over a week was extensive and this is reinforced by the results given in Härdle and Kirman [1993]. Two of the possible explanations for such dispersion are the effect of differing market volume, and the effect of price changes over the day (typically thought of as diminishing). We shall examine both of them.

### *3.2 Variations in Market Activity*

There are clear differences in the level of market activity. Some days are less active (Sunday is very inactive, for example) and the relative activity varies over the month.

A first and obvious question is to what extent is the level of prices correlated with the level of activity in the Market ? We tested this by looking at the correlation over the month of July between the daily average price charged and the corresponding number of transactions carried out for a selection of fish types, involving both a large and a small number of transactions. We were unable to find any significant differences across types of fish in these correlations.

A second observation is that buyers and sellers differ considerably in their level of activity. Distributions of numbers of transactions for buyers and sellers are illustrated in Figures 5 and 6. The number of transactions is influenced, for sellers, by the relative degree of specialisation and for buyers by two factors. Firstly, there is the nature of the buyers, activity (fish retailer, supermarket, restaurant) and, secondly, there is the extent to which buyers search. The latter merits some discussion.

### *3.3 Searchers and Loyalists*

In Kirman and Vignes [1991], and Kirman and McCarthy [1990] we noted that, even looking at one week's data, there seemed to be a very clear distinction between those buyers who visited [4] few sellers and those who "shopped around" extensively. We suggested then that this division could be considered by buyers as an "evolutionarily stable strategy".

4. Visited is not quite accurate since we have no record of visits which did not result in transactions.

This is, no individual would have an incentive to shift from being a "loyalist" to being a "searcher" or vice versa. Such a situation could be collectively rationalisable, in the sense that the externality produced by searchers for loyalists is internalised[5] . Thus different buyers would be using different strategies but none would have an incentive to change.

More recently we have taken into account the fact that buyers visit the market with different frequencies and examined how the distribution of number of sellers visited would look if buyers simply chose amongst sellers with the same uniform probability. Although this did not give a very good fit, if we take account of the fact that when all sellers are equally attractive a buyer could visit his previous supplier with probability one half and choose a new one at random with the same probability then the fit was greatly improved. Now, if we assume that there are some costs to switching suppliers then the probability of returning to the same seller would be correspondingly higher. The question is, can we find a value of this probability which would give us a good fit of the observed distribution ? The somewhat surprising result is that we can obtain a perfect fit by the appropriate choice of this probability. Thus if all buyers return to their usual seller with p= 0.905, the distribution of visits is precisely that observed in reality. Thus in this alternative explanation all buyers have identical behaviour once they appear on the market but the difference in the frequency with which they do so gives rise to the observed asymmetric distribution.

### *3.4 Different price behaviour for different sellers*

Participants in the market sometimes refer to the existence of sellers who systematically charge higher prices. In Kirman and McCarthy [1990] we tested this by ranking sellers by average price charged for a given fish for each day and then doing a rank-correlation test between days. When the correlation was significant, it was negative. Thus a high priced seller one day was more likely to be a low priced seller the next. However, this test does not completely rule out the existence of sellers with systematically different mean prices since the effect of those who vary their prices a great deal might be enough to dominate the effect of those who maintain very stable prices. If these sellers are such that 1 and 2 systematically charged the highest and lowest prices and change places from day to day, then we would obtain our result even if seller 3 charged the same price every day and that price were above the average of those charged by 1 and 2. An alternative explanation for the existence of high average price sellers would be precisely that they have lower variances. Thus risk averse buyers would frequent such sellers.

We tested this by looking at the correlation between the average transaction price for a particular type of fish and the corresponding variance in price (1) over sellers and (2) over buyers. In the case of sellers, of the 8 fish types[6] tested, 5 had significantly negative correlations while in the remainder of cases the correlation was insignificant. On the buyer side 6 fish types displayed significantly negative correlations.

### *3.5 Prices Over the Day*

It is commonly argued that as the day passes, prices will decline. In our model it is clear why this should not necessarily be the case. Consider the situation in which there are two sellers and two buyers in the market in period $T\text{-}1$ . If one of the sellers, say 2, has no more of a given fish market whilst the other has a stock then the following may occur. Buyer 1 visits seller 2 with a demand $q(p)$ . Now if buyer 2 who will visit seller 2 with probability 1/2, $T$ has a demand which is $nq(p)$ then clearly the price charged to buyer 1 in time $T\text{-}1$ may be lower than that charged to buyer 2 at time $T$.

We tested the proposition of declining prices for different types of fish for individual sellers by fitting a linear trend model to the prices recorded by an individual seller over one day for a particular fish type. This test was carried out for the 8 fish types mentioned above and 10 sellers for various days of the month. In no case was the trend in prices found to be significant.

One interesting observation is that a seller who is known here to leave the market early, say at Time $T\text{-}x$ may be discriminated against. At time $T\text{-}x$ the seller can charge the optimal price without fear that the buyer sell elsewhere.

5. It might seem that since there is price discrimination, searchers will not affect prices charged to loyalists. However, the fact that searching leads searchers to change their demand will influence indirectly the prices sellers wish to charge to non-searchers.
6. The set of fish types used for illustration here is a subset of those which were involved in a large number of transactions over the month, an important factor for carrying out some of the statistical tests referred to below. The fish types are : #40 Conger Eel, #44 Whiting, #116 A type of Eel, #118 Lemon Sole, #196 Red Mullet, #214 Sole, #224 Sardines, #250 Trout.

However, at time *T-x-1* the preceding seller does the same and so forth recurrently. By this reasoning, the buyer will have to pay the monopoly price from the outset. This would explain why fish costs more in the interior of France rather than the usual explanation of transport costs. There is a flaw in this reasoning since otherwise it would apply to all buyers since they all face a fixed horizon *T*. The flaw is that the "monopoly" price varies depending upon the history or the day of the seller and that is therefore different between sellers at any point in time. Thus the buyer has an interest in staying in the market. However, this may be a partial explanation for the higher prices paid by those who leave early.

### *3.6 Aggregate "Demand"*

In economics, aggregate behaviour is often tested to see if it meets restrictions that can be derived from individual maximising behaviour. Thus it is common practice to treat data arising from aggregate purchases of some commodity over time as if these were the expression of the competitive demand of some representative individual. This approach involves a number of implicit assumptions, in particular that the underlying micro-data observed can be thought of as corresponding to individual Walrasian demand, and furthermore that aggregation considerations do not invalidate the use of restrictions derived from individual behaviour.

In Härdle and Kirman (1993) we find empirically that, for the Marseille fish market, properties which we show to hold at the aggregate level and which might be thought of as "downward sloping demand curves" are not derived from similar properties at the individual level. Furthermore, using the model specified above, we show that there is no theoretical reason to expect any such simple relation between individual and aggregate behaviour. In this we are following directly in the line of work by Becker (1962) [7] who showed that downward sloping demand curves at the market level could be derived from random individual choice behaviour subject only to a budget constraint. Whereas he summarised his result as saying that "households may be irrational and yet markets quite rational", a better summary of our results would be that "sophisticated and complicated individual behaviour may lead to simple aggregate properties."

In particular, we examined this problem by looking at the properties of the purchases of particularly perishable goods, the different types of fish, for which we have the data already described, at the individual level, from the Marseille fish market. Although, as I have mentioned, fish markets have been widely used as an example in the economic literature, we argued, in that paper, that, for several reasons, it is inappropriate to think of purchases on such markets as corresponding to Walrasian demand. In the context of the theoretical model it is clear that the quantities "demanded" or "supplied" by the individuals in question cannot be expected to correspond to those that would be "demanded" or "supplied" by the standard individual in a competitive market. Instead we use a more appropriate theoretical notion, that of "strategic demand and supply".

With this, the appropriate equilibrium concept can be defined and corresponds to a non-degenerate price distribution (see Diamond [1987], Butters [1977]). For the use of the theoretical model to be justified and if we are to be able to use data from the whole period that we study, it should be the case that the observed price distributions remain fairly constant over time. If this is the case, then one can think of the market as repeating itself from day to day, or at least from week to week. We test for the intertemporal stability of the price distributions for some representative types of fish. In particular, it should be noted that we did this without imposing any a priori restrictions on the form of the distributions. Then, having established that these do indeed remain constant, we used non-parametric methods to fit two different aggregate price quantity relations and found that these relations, in contrast to those at the individual level, exhibit monotonicity once a certain class of observations is identified and removed. The important thing to notice is that non parametric methods are, in a certain sense, the least favourable to monotonicity since they will pick up any small non monotonic deviation and the resultant smoothed curve will preserve this. The counterpart is that this enables one to identify the observations that create the problem, in our case late transactions whose price varied substantially, depending, amongst other things on the total amount of fish available on the market on the particular day in question.

7. This idea has been developed recently by Gode and Sunder [1993].

## 4. CONCLUSION

The data from the fish market that we have studied are unusually rich and provide a number of interesting possibilities for further investigation. However, what is clear from our analysis is that the notion of an equilibrium price system is very complicated and rather far from standard competitive markets. Simply because a large number of buyers and sellers are gathered together dealing in the same product at the same time does not mean, for example, that the price of that product will be the same in simultaneous transactions. In the particular market that we have studied, no prices are posted and sellers know buyers' characteristics. Changing these two basic features would understandably modify many of the conclusions and it would be of interest to compare the outcomes of this market with those of markets organised on an auction basis for example.

# Relative Price Variability in Fisheries some Policy Implications

**Chris Ioannidis** *

Cardiff Business School, University of Wales, Aberconway Building, Colum Drive, Cardiff CF1 3EU, U.K.

ABSTRACT

*The paper comments on the currently operating intervention scheme and suggests that it is important to distinguish the sources of price changes. It then investigates the size-specific price variability in fisheries and finds evidence of significant non-proportional price variation. It goes on to suggest a method to isolate the influences of demand on the size-specific price changes, and suggests a compensation system based exclusively on insuring producers from demand fluctuations only. An empirical example, is provided, using French data for Cod and Haddock. Significant differences in the fluctuations of demand for each size were found.*

## 1. INTRODUCTION

It is well known that a result of fluctuating prices at fish auctions at the quays, is the intervention of the authorities in the market to stabilise prices thus ensuring 'stable' incomes for the producers.

Within the European Community the system in place is the withdrawal price scheme which is operating since the mid 70's. An economic analysis of the system is developed in Young (1984) and the ramifications of the system's operations for both producers and consumers are discussed.

## 2. THE CURRENT POLICY REGIME

The point of departure for the operation of the scheme is the 'guide price' which is a notional price in (ECU/tonne) and it applies throughout the community. The 'guide price' reflects the prices that the Commission expects to be attained.

* The author would like to thank Paolo Maggioni and Nigel Driffield of the Cardiff Business School for their help and advise. Remaining errors are of course the author's responsibility.

These 'expectations' are based on passed experience and possibly some heuristic forecasts of future trends. Once the 'guide price' is established the 'withdrawal price' is then derived and it is guarantied as the minimum price that the product will be sold, it therefore acts as the 'floor price' at the auction. If the price of fish for human consumption were to fall below the 'withdrawal price' the fish whose price has thus fallen, is then removed from the market at this price. Once bought at the 'withdrawal price' it does not enter the food chain but it is processed for animal feed. It must be emphasized here that the 'withdrawal price' does not fully reflect the amount that producers receive. In fixing the 'withdrawal price' the Commission takes into account the 'guide price', a 'quality factor' and the 'regional coefficient'. What the fishermen actually receive is the 'compensation price' which is a proportion of the 'withdrawal price'. Young (1984) explains in detail how this proportion varies as a function of landed quantities. The use of the Green rate in setting the 'guide' and 'withdrawal' prices provides for considerable stability in terms of domestic currency insulating producers from spot rate variability. The sterling price received by British fishermen will be raised only if the Green pound is devalued. The graphical analysis depicts the impact on producers' incomes when the withdrawal price scheme is operational (graphs 1a, 1b).

As it is commonly assumed the supply of fresh fish at any given time is price inelastic, Q(s). For any given demand DD, if the equilibrium price P(e) is below the 'withdrawal' price P(w), the quantities allocated to human consumption will be Q(a) and Q(a)Q(s) represents the quantities to be withdrawn. By varying P(w) for any given volume of demand and supply conditions we can establish the 'withdrawal price' schedule WW in figure 1a. But unlike producers of other agricultural commodities fishermen do not receive the 'withdrawal price' for their produce but a variable proportion of it, the compensation price. The BE schedule, in figure 1B, represents such relationship between the compensation price and the level of withdrawals. Thus for any given intervention price P(w) the fishermen actually receive P(c), in figure 1a. Total revenue can now be calculated as the sum of those revenues raised by selling fish for human consumption (P(w)*Q(a)) and the revenues accrued from the withdrawn fish (P(c)*Q(s)Q(a)). Fishermen vial their lobbying organisation attempt to influence the policy instrument as it is vital to their interest. From their point of view, they will asking for a withdrawal price taking into account the following elements :

$$P(w) = F(-e(d), -dP(c)/dw, -Q(s)) \quad (1)$$

where e(d) is the elasticity of demand, the second term captures the rate at which the compensation price declines in response to withdrawals, and finally Q(s) stands for total landings. The sign below indicate the direction of the response on P(w) due to a change in any of the three elements. In the case of the UK and France the role of imports in increasing total available supply is crucial in maintaining lower than otherwise 'withdrawal prices'. In the UK where cod and haddock are by and large the main species demanded by consumers, the price elasticity of demand for domestic landings is being estimated at -3.03 and -1.55 respectively Ioannidis and Whitmarsh (1989). For other less popular species the substitution opportunities increase and the implied demand price elasticities are considerable higher.

## 3. SOURCES OF PRICE VARIABILITY

The scheme, as it is currently working does not discriminate what causes the equilibrium price to fall below the 'withdrawal' price. The price fall can be either due to higher than anticipated supply or lower than anticipated fall in demand. In a recent paper Van Kooten and Schmitz (1988) extent the analysis of commodity price stabilisation to the case of nonstorable commodity, under uncertainty. The problems of price stabilisation for storable agricultural commodities has been addressed by Oi (1961) and Massell (1969) among others.

The following discussion, which aims to highlight the importance of the source of the price shocks, relies on Van Kooten and Schmitz (1988).

Consider initially the case of price variability caused due to demand fluctuations. Assume that there are n probable states of demand, denoted by D(1),...,D(n). Risk neutral producers will attempt to supply(ex-ante)

$$S = S(f(i)\ P(i))\ i = 1,...,n \quad (2)$$

where f(i) is the probability associated with price P(i). The stabilisation rule can thus be set as :

$$P(E) = \Sigma_i \, (f(i)*P(i)) \tag{3}$$

thus if the producers were to operate a buffer fund, the fund's expected revenue will be given by :

$$\Sigma_i \, f(i) \, S(P(E) - P(i)) = 0 \tag{4}$$

So the fund is actuarial sound and the scheme sets producers' output such that producers' price will be P(E) and output will be given by (2) (see graph 2).

As the scheme is actuarial sound there is no transfer from consumers to producers. With risk averse producers the existence of such policy results in a Pareto improvement as it reduces price variability and thus improves the welfare of the fishermen.

Now consider the case where price variability is due to unpredictable fluctuations of the supply. The quantity offered to the market from one period to next varies with known probability j(i). Given the position of the demand curve the expected price will be given by

$$P(E) = \Sigma_i \, (j(i) \, P(i)) \tag{5}$$

and the realised supply will be

$$S = S(P(E),U) \tag{6}$$

where U is a random variable with known distribution. The equilibrium will be characterised by the distribution of prices and quantities such that the market clears ex-ante. If the aim of the policy is set prices at P(E), producers will act as in the previous case and under the competitive assumption and rick neutrality will plan production as in (2). However their expected revenues will be higher with the scheme than without it. The Graph 3 depicts the situation

Consider the case of two equiprobable states of supply S1 and S2, for any given downward sloping demand curve DD, the expected revenues for the fund and the producers can be calculated as follows.

Without the scheme the expected producers' revenue is given by :

$$E(RV1) = (1/2)*(P(1) \, Q(1) + P(2) \, Q(2)) \tag{7}$$

but by setting P = P(E) their revenue will now be

$$E(RV2) = (1/2)*(Q(1) \, P(E) + Q(2) \, P(E)) = (1/2)* \left(E(RV1) + .5 \, [(Q(1) - Q(2))*(P(1) - P(2))]\right) \tag{8}$$

under normal demand conditions

$$E(RV1) < E(RV2) \tag{9}$$

Thus there is a net transfer of resources from consumers to producers.

## 4. RELATIVE PRICE VARIABILITY

The above discussion helped to the fact that price stabilisation of a non storable commodity which does not discriminate between demand and supply shocks responsible for price variability has quite important budgetary implications for the authorities.

Most landing prices for fresh fish are determined in competitive auction markets. Prices change because of the discrepancies between the actual and expected values of the conditioning variables. Each species landed is further separated into standard sizes, depending of the weight of the individual fish. At the quay auctions the final quoted prices

are size specific and their weighted combination is referred to as the 'species price'. As the fish vary in size and weight according to their classification their yield will also vary. The differences in the yield will generate distinct demand conditions, depending on the nature of the final user. The demand for 'small' and 'unclassified' fish by processing enterprises will be stronger compared to those of restaurateurs and fishmongers. Demand conditions for each particular buyer may be changing according to seasonal factors, advertising campaigns and other changes in tastes. Yet, as it was previously discussed, policy measures tend to ignore these differences and the 'average price' for each species is used as a guide-line for intervention. The use of such average disguises the various pressures due to demand changes and 'confuses' them with possible size specific supply changes.

The 'average price' of a species j categorised into k sizes can be written as :

$$P(j, t) = \Sigma_{i=1,k}\, w(i, t)\, P(j, i, t) \quad i = 1,...,k \tag{10}$$

the weights w(i, t) are taken to be proportional to the contribution of landings of size i to total landings. P(j, i, t) is the size specific price for species j.

Two sources of disturbance are now present :

(i) variations the total catch and in the size distribution of landings

and

(ii) variations in the size specific prices due to changes in the size specific demand conditions.

In the standard Divisia price index formation changes in the 'average price' of species j can be written as :

$$DP(j, t) = \Sigma_{i=1,k}\, w(i, t)\, DP(i, j, t) \tag{11}$$

where

$$DP(i, j, t) = \log (P(i, j, t)) - \log (P(i, j, t - 1)) \tag{12}$$

A simple measure of relative price variability can be given by the weighted sum of squared deviations of the size specific price changes from the average 'species price.

$$VP(j, t) = \Sigma_{i=1,k}\, \{(DP(i, j, t) - DP(j, t)\}^{\wedge} 2 \tag{13}$$

Thus VP(j, t) measures the non-proportionality of price movements, for if all prices change by the same rate, the quantity VP(j, t) will be zero. The measure will be larger the more non-proportional the price changes become. In a previous study Ioannidis(1989) tested for the existence of relative price variability, using the regression

$$VP(j, t) = c0 + c1*DP(j, t) + u(j, t) \tag{13a}$$

has found significant non-proportional variations for cod and haddock in Scotland for the period 1983-1988, as the estimate of c1 was found positive and significantly different from zero.

This is taken as prima-facia evidence that there exists important differences in the demand conditions of each size.

If the authorities wish to compensate fishermen for the variations in price which are exclusively due to demand conditions then some appropriate measure is needed.

## 5. A 'NEW' SCHEME

The authorities observe a single signal, the change in price and on the basis of this intervene, however to compensate fishermen for temporary fluctuations in supply or its composition is not desirable. Fishermen should compensated for fluctuations in demand but not for those in supply. The task here is to develop an approximation in order to measure the contribution of price changes due to shifts in demand.

Consider the market situation at t + 1, where S(i, t + 1) fish are landed and the market clearing price is quoted at P(i, t + 1). Assuming linear demand curves (which are non-integrable) let me postulate a simple linear relation between prices and quantities

$$P(i, t + 1) = a(i, t + 1)*S(i, t + 1) \quad (14)$$

where a(i, t + 1) is some measure of the slope of the demand curve at t + 1, which remains unchanged along the curve for this time period, t + 1. The authorities have observed from the previous period, t, the market clearing prices and quantities traded, (here we may assume that at this period the 'equilibrium price' was the one 'desired' by the authorities). The question the authorities will ask is the following : ' If the fishermen had not altered their supply, therefore if S(i, t) = S(i, t + 1), given the now (t+1) prevailing demand conditions, what would the price be ? '.
The answer to this question can be calculated as follows

$$P^*(i, t) = a(i, t + 1)*S(i, t) \quad (15)$$

Now if P*(i, t) < P(i, t) then the fishermen will be compensated to the tune of [P(i, t) - P*(i, t)] S(i, t), this part of the price fall can be attributed to a fall in demand. The graph 4 depicts the situation.
In this scheme fishermen will be compensated even if the final price of the fish has risen, provide that demand has fallen, as in Graph 5.
As the fishermen will not be expected to pay a levy if P*(i, t) > P(i, t) a net contribution from consumers to producers will take place. In this scheme the authorities will not react immediately as prices are falling but they will retrospectively compensate producers for lost revenue due to falls in demand. Such a income stabilisation program will also act as a deterrent to overfishing. For if prices were to fall because in the current period (t+1) producers have overfished no compensation will be paid despite the fall in prices if demand has remained unchanged. Furthermore if fishermen break net size regulations and land more 'small' fish than anticipated they will drive down their prices but again no compensation will be paid.

## 6. SOME EMPIRICAL EVIDENCE

Using monthly data covering the period 1983m1 to 1988m12 for cod and haddock, by size, measures of relative price variability were constructed vpc,vph.
Running the same regression as in (13a), it was found that the price of cod did exhibit significant relative price variability and haddock prices also did show evidence of non proportional price changes.
To investigate whether such phenomena were due to differential changes in demand (by size) the following method was followed employing the methodology outlined in section 5. To estimate a(j, t + 1) a 12 period rolling regression was run using the linear function for each size of both species.

$$P(j, i, t) = c0(j, i, t) + c1(j, i, t)\ S(j, i, t) + U(j, i, t) \quad (16)$$

the series of the rolling coefficients are collected and the series of imputed prices due to demand only changes are computed. These are then compared to the actual quoted prices to isolated the exclusive influence of demand factors on price chamges. The graphs 6 and 7 show that within each of the species there are considerable differences in the movements of demand causing prices to vary over and above fluctuations due to changes in the quantities landed. There is no doubt that demand movements across size of the same species show a considerable amount of comovement between the computed P*(j, i, t), but to perceive them as identical will be mistake. An intervention scheme will have therefore to be fine enough to discriminate and award compensation only to those sizes whose prices have fallen due to adverse demand changes.

## 7. CONCLUSIONS

In this paper an attempt was made to quantify the differences between the demand and supply size-specific shocks. It was argued that compensation schemes based on 'average' prices are not based on sufficiently detailed information and

consequently are thus more expensive than they need be. As the regulatory framework of the Community imposes severe restrictions on the quantities to be fished and the nature of the capital equipment used they control both total supply and its size composition. To compensate producers for temporary fluctuations in supply which is already regulated seems to be rather misguided. Fishermen should be insulated from fluctuations in demand over which there is no control. It was asserted that Demand conditions may vary across sizes of the same species thus requiring separate monitoring. The empirical evidence presented here, using French data, supports the basic assertion that each size for the same species faces demand conditions are sufficiently different, justifying the use of a more information intensive scheme.

# The Market Interaction of Wild Salmon Fisheries and Salmon Aquaculture

**Christopher S. Wright[a] and Parzival Copes[b]**

ABSTRACT

*The rapid expansion of farmed salmon production during the 1980s has raised concerns among many fishermen and analysts that aquaculture may supplant the commercial fisheries of wild salmon. However, dramatic as the increase in farmed output has been, it neither constitutes evidence that farmed salmon is currently replacing wild harvests, nor does it give reason to believe that such a replacement will soon ever occur.*

*This paper provides a framework for examining this and related concerns by modeling both industries and examining how they interact under a variety of wild fishery management regimes.*

*Under all scenarios considered likely, wild-salmon supply was either inelastic or increased as salmon prices fell. This counter-intuitive response arises from the common- property resource condition of wild fisheries where falling fish prices reduce activities that dissipate resource rent and/or reduce the market value of fishing rights.*

*The results indicate that lower salmon prices generated by competition with farmed salmon will tend to force rationalization on wild fisheries. While this rationalization may bankrupt individual fishermen and/or make various fishing methods non-viable, the wild salmon supply will tend to be inelastic or may even increase as prices fall. Most of the surplus generated by this rationalization is likely be in the form of consumer surplus and thus not to the fiscal benefit of either governments or fishermen.*

*If the basic premises and formulation of the models in this paper are valid, aquaculture (as an industry) is the source of salmon at the margin, as compared to the wild fishery. Thus, while farmed salmon may determine the price of salmon, it is unlikely to supplant wild salmon via price competition.*

## 1. INTRODUCTION

The rapid expansion of farmed salmon production during the 1980s raised the question : "Will aquaculture supplant commercial fisheries of wild salmon ?" Cunningham, et al. (1985, p. 311) observed that "Moiseev (1977) and others have

predicted that ultimately aquaculture will replace capture fisheries." Larkin (1990, p.68) noted that "...there is evidently a trend toward farming sea foods rather than chasing after them." Bjorndal (1990, pp.8-9) predicts that by 2000 AD farmed salmon may account for a 65 to 85 percent share of its market and asserts that "...in a few years farmed salmon will dominate the markets for Atlantic, coho and chinook salmon."

This paper gives a theoretical analysis of the long-run market interaction between a now well-developed salmon aquaculture industry and the large North American Pacific salmon fishery. The wild salmon fishery, historically, has been burdened by the many external diseconomies of a *common use resource.*[1]

This has resulted in a severely suboptimal industrial structure that dissipates enormous potential resource rents (Crutchfield and Pontecorvo, 1969). This, however, has left open opportunities for large improvements in productivity through rationalization, which allows the wild salmon fishery to accommodate to much lower prices generated by competition with the salmon farming sector.

### *1.1 The elements of the model*

This study uses a *hierarchical general system approach* where influences from outside the scale of the model are embodied by assumptions and modules portray logical and/or useful (but not necessarily physical) components within the system. Each module is represented by a single equation or a set of simultaneous equations in which lower scale details are represented by parameters or other assumptions. Interactions between modules are captured in the form of variables that are *output* of the *signaling module* and *input* to the *receiving model.*

This paper arranges the elements of a stylized salmon market into three modules--*salmon demand, wild fishery supply* and *aquaculture supply.* Detailed descriptions of the latter two modules are available from the authors, as appendices (equations with an A or B prefix are from those appendices).

## 2. THE DEMAND FOR SALMON

While, salmon demand is a complex amalgam of the demands of several user groups (DeVoretz, et al., 1991a, pp.1-2), this paper makes the simplifying assumption that salmon is a uniform product having an aggregate demand of the form :

$$P = ae^{-bQ} \tag{1}$$

Q = quantity demanded
P = observed market price
a, b = parameters
*e* = exponent

## 3. THE WILD FISHERY

In keeping with a simple general-model theme, the wild fishery is assumed to involve one stock, harvested by one gear type, in a common-use resource fishery. Both open access and limited entry conditions will be explored. As shown in Appendix A, the equilibrium harvest at a given effort level may be defined by :

$$\overline{H}^{\circ} = (\delta / \beta)\ln [\alpha (1 - qE)] / [1 / (qE) - 1] \tag{A5}$$

$\delta$ = landed portion of M

1. The authors suggest that *common use resource* is a more apt term than the conventionally used *common property resource*, as fish resources are often unowned rather than owned in common.

$\overline{H}^o$ = escapement allowed catch (EAC)
M = annual fishing caused mortality
q = catchability coefficient
E = total effort
α, ß = parameters

*3.1 Wild fishery : supply curve in an open-access fishery*

The competition in an open access fishery will tend to drive out vessels that are not cost-efficient. As a result, all vessels tend toward the following minimum cost configuration :

$$f^* = g^{-.25}/\tau \tag{2}$$

g = effective fishing season length (part of a year)
f* = optimal fishing power per vessel[2]
τ = parameter reflecting economies or diseconomies of scale

The vessels in a fishery can be defined by substituting the RHS of eqn (2) into eqn (A8) and rearranging the result to :

$$V^* = E\tau g^{-.75}/m \tag{3}$$

V* = vessels associated with f*
m = technology parameter

And the total cost of fishing can be defined by substituting the RHS of eqns (2) and (3) into eqn (A9) to produce :

$$C_F^* = (\Phi + g\Omega)\, E\tau g^{-.75} e^1/m \tag{4}$$

$C_F$* = cost of effort at f *
Φ = fixed cost of a fishing vessel
Ω = season related fixed cost of fishing power

When the escapement is binding ($S \leq S^0$), the fishery managers limit the fishing effort by regulating the effective length of the season and eqn (4) becomes :

$$C_F^* = (\Phi + g\Omega)\, E^0\tau g^{-.75} e^1/m \tag{4a}$$

In eqn (4a), the fishing effort is fixed at $E^0$ and the season length is a variable.

In an open access fishery all resource rent is dissipated by increased effort costs and/or decreased harvests. Thus, eqn (A6) can be set equal to eqn (4). That result, if the escapement is not a binding constraint, can be reorganized to define the supply price of salmon as a function of fishing effort :

$$\overline{P} = \beta(\Phi + g\Omega)\tau\, [1/q - E\,]\, e^1/(m\,\delta \ln [\alpha\,(1 - qE)]\, g^{.75} \tag{5}$$

The harvest associated with that price/effort combination is defined by eqn (A5) :

$$\overline{H} = (\delta / \beta) \ln [\alpha(1 - qE)] / [1 / (qE) - 1] \tag{A5}$$

If the escapement is a binding constraint, eqn (5) is still valid, but fishing effort becomes a parameter (eqn (A4b)).

2. If the AC of f (eqn (A9)/f) is differentiated with respect to f, that differential can be set equal to nil and reorganized :

$$d(C_f/f) / df = V(\Phi + g\Omega)\, e\, [\, g^{.25}\tau f\,]\, (\, g^{.25}\tau f - 1\,)\, f^{-2} = 0$$

$$f^* = g^{-.25}/\tau$$

$$\overline{E^{\circ}} = (1 - e^{\beta S^{\circ}} / \alpha) / g \qquad \text{(A4b)}$$

$E^0$ = target effort

$S^0$ = target number of spawners

and season length is an independent variable. The resulting supply curve of an open access fishery is shown in Figure 1. It is a *backward-bending supply curve* (Copes, 1970). However, the *Ricker surplus-yield curve* (eqn (A1)) that underlies the supply curve causes several differences between that supply curve and Copes' (1970) supply curve. Specifically :

- At low prices the average cost of supplying salmon falls. This occurs because, as fishing effort rises from nil, recruitment initially increases until the maximum recruitment is attained (point B in Figure 1).
- The supply curve is strictly convex (with respect to the origin) at any point above MSY, where the escapement is not binding. Where escapement is binding, the season is set to prevent the harvest from rising and cause the salmon supply curve to become infinitely inelastic with respect to price.
- These two features tend to make the supply curve very inelastic at high prices and very elastic at low prices.

In Figure 1, there are two open-access equilibriums. The one that occurs when escapement is not binding is labeled OAE and the one that occurs when escapement is binding is labeled *EAC shifted OAE* to show that is defined in part by the *escapement- allowed catch* [3].

### *3.2 Wild fishery : supply curve in a limited-entry fishery*

If there is a limit on the number of vessels licensed to fish in a fishery, the vessel owners will seek to maximize their share of any resource rents by stuffing inputs into their vessels. If a vessel's share of the total fishery revenue is proportional to its share of the effort in the fishery then (based on eqn (A8)) the income of a vessel can be defined by :

$$Y_i = gmf(PH^{\circ} / E^{\circ}) \qquad (6)$$

and a vessel's net income can be defined by dividing eqn (A9) by the number of vessels and deducting the RHS of that result from the RHS of eqn (6) :

$$\pi_i = gmf(PH^0 / E^0) - (\Phi + g\Omega)\, e\, [g^{.25}\tau f] \qquad (7)$$

$$d\pi_i / df = gm(PH^0 / E^0) - g^{.25}\tau\, (\Phi + g\Omega)\, e\, [g^{.25}\tau f] \qquad (8)$$

If the RHS of eqn (8) is set equal to nil it can be rearranged to :

$$f^{\$} = g^{-.25} \ln [g^{.75}(m/\tau)\, P(H^0/E^0)/(\Phi + g\Omega)]/\tau \qquad (9)$$

or to :

$$P = g^{-.75}(\tau/m)(E^0/H^0)(\Phi + g\Omega)\, e[g^{.25}\tau f] \qquad (9a)$$

When the RHS of eqns (A8) and (A4b) are set equal, the result can be reorganized to :

3. It is interesting to note that the total fishing power at the *escapement-allowed* open-access equilibrium (2,339 units--Table 2, Appendix C) was 3.6 times the fishing power at the natural open-access equilibrium (645.2 units--Table 1, Appendix C). The result is consistent with Wright's (1991, pp. 87-89) results.

$$f = (1 - e^{\beta S} / \alpha) / (qgmV) \quad (10)$$

If the RHS of eqn (10) is substituted into eqn (9a) the result defines the supply price as a function of escapement, fishing effort, harvest, vessel numbers and season length :

$$P = \tau (\Phi + q\Omega) g^{-.75} e [\tau g^{-.75} (1 - e^{\beta S^0} / \alpha) / (qmV)] (e^0 / H^0) / m \quad (11)$$

The fishing effort and the harvest can be eliminated from eqn (11) by substituting in the RHS of eqns (A4a) and (A7) :

$$P = \tau (\Phi + q\Omega) g^{-.75} e [\tau g^{-.75} (1 - e^{\beta S^0} / \alpha) / (qmV)] / [\alpha e^{-\beta^\circ} qm\delta S^0] \quad (12)$$

In the open-access salmon fishery in subsection 3.1, eqn (5) is the average social cost (ASC) and the marginal private cost (MPC) of supplying wild salmon. In the limited entry fishery, described in this subsection, eqn (5) is the perceived MPC.[4]The average cost of supplying salmon was defined by dividing the result of eqn (A9) by the EAC (escapement-allowed catch).

The limited-entry fishery salmon supply curve (Figure 2) appears to be an exact duplicate of the open-access supply curve (Figure 1). This occurs because where limited entry is binding (above point A) the supply curve is infinitely inelastic, as a result, any visual differences are lost in that infinity.

In a limited-entry fishery, not all resource rent is dissipated. Fishermen supply salmon according to their perceived MPC. In an open-access fishery (Figure 1) the MPC equals the AC. In a limited-entry fishery (Figure 2), imperfect substitution for the limited input (e.g. vessels) drives the MPC above the AC and fishermen will only add inputs as long as the MPC is below the landed price of salmon.

The Figure 2 supply curve can be divided into three portions, for prices :

i) above point A, escapement and limited entry are binding constraints in the fishery ;

ii) between points A and B, escapement is a binding constraint ;

iii) below point B, neither escapement nor limited entry is a binding constraint.

The shape of the limited-entry fishery salmon supply curve is identical to that of the open-access fishery. As a result, the conclusions with respect to price and elasticity of the supply curve are identical to those of the previous subsection.

## 4. THE CONCEPT OF A RESIDUAL INDUSTRY

If the wild-fishery and salmon-farm outputs are perfect substitutes and there is no producer surplus in either industry (Copes, 1972) then, the output from the industry with the (potentially) lowest cost of supply will always be sold and the other industry can be characterized as catering to the residual market.

If collusion and/or oligopoly is absent, the marginal output in the market aligns with the market price and, by definition, the residual supplier/industry supplies the marginal output in a market. Thus, the market price is determined by the actions of the residual industry and that market role reflects weakness rather than strength.

The question of which industry will, in the long run, be the residual supplier of salmon is empirical in nature. However, there are at least two reasons for treating aquaculture as the residual supplier : 1) salmon aquaculture is a relatively new source of salmon and has tended to act as a residual supplier ; 2) wild salmon, that can be had for the cost of harvesting in a gauntlet fishery, is likely (at some scale of output and/or some gear type) to be cheaper than output that must be fed and otherwise husbanded over an 18- to 60-month lifespan.

4. The MPC of supplying fish is extrapolated on the assumption that the relations that held in the fishery in the previous season will hold in the current season. Fishermen are assumed to not know the actual future marginal cost of supplying fish (i.e. that would involve, among other things, a simultaneous precognition of how other fishermen will act and how those actions and their own actions will affect the fishery).

## 5. SALMON FARMING : THE RESIDUAL DEMAND

If aquaculture is the residual supplier of salmon then the farmed salmon industry perceive the demand for their product as the gross demand (eqn (1)) less the wild fishery supply (Tables 3 and 4).

The residual supply curve (Figure 3) has four distinct zones :

i) To the left of point A, the residual demand is relatively elastic.

ii) Between points A and B, the elasticity of the residual demand declines because the wild harvest is increasing (i.e. effort is low enough that the target escapement is not a binding constraint on the wild harvest).

iii) Between points B and C, the elasticity of the residual demand increases because the salmon prices are below the wild fishery MSY price (i.e. the wild salmon supply is falling).

iv) To the right of point C, prices are below the minimum cost point on the wild-fishery supply curve (point B, Figure 1) --this causes the residual demand curve to shift to the gross demand curve (eqn (1)).

### *5.1 Salmon farming : the salmon supply curve*

In Appendix B, the long run farmed salmon supply curve, for the sake of simplicity, is assumed to be infinitely elastic (though input restrictions, such as site availability, may cause the supply curve to increase slightly with quantity).

$$P^* = MC^* = AC^* = \$3.0838/kg \qquad (B15)$$

## 6. HOW WILL SALMON AQUACULTURE AND THE WILD FISHERY INTERACT ?

The minimum supply cost of farmed salmon is likely the most important determinant of salmon prices in the long-run. As the farmed salmon additions to output drive down prices, much of the potential social surplus in fisheries may be realized in the form of consumer surplus. In the process, aquaculture tends to force the wild fisheries sharing a market to rationalize in order to remain competitive.

If the long-run minimum supply cost of farmed salmon should ever fall below the minimum supply cost of the rationalized wild salmon fishery, the market replacement of wild salmon by farmed salmon may become a reality. Given the great potential for cost reduction through rationalization in wild salmon fisheries (Crutchfield and Pontecorvo, 1969), this eventuality appears unlikely for the foreseeable future. It is conceivable though, that some higher cost smaller components of the North American salmon fishery would be abandoned owing to competition from farmed salmon.

Figure 3 shows how salmon farmers should perceive their market :

i) At high prices, where the backward bending portion of the wild salmon supply curve does not come into play, the residual demand curve appears to be normal (see the curve between the Y-axis and point A).

ii) As prices fall low enough to activate the backward bending portion of the wild fishery supply, the increase in wild salmon supply appears as a decline in the elasticity of the residual demand (see the curve between points A and B).

iii) As prices fall below the wild fishery MSY price, the fall in wild salmon supply appears as an increase in the elasticity of the residual demand (see the curve between points B and C).

iv) Only if prices fall below the wild fishery minimum cost (point B, Figure 1) will the residual demand shift to the gross demand--as at point C, Figure 3, the wild fishery is abandoned.

Several factors not directly considered in this analysis will tend to make the *residual demand elasticity effect*, observed between points A and B (Figure 3) more pronounced and may increase the range of prices over which it is observed.

(i) Salmon fisheries are often exploited by several types of fishing gears[5]. Each gear type has a different cost profile. Thus, the number of viable gear types in a salmon fishery will tend to fall as prices fall. This should have several effects :

- In salmon fisheries, higher cost gears may impose cost increases on intrinsically more efficient gears via external diseconomies (e.g. interception). Restrictions on higher- cost *intercepting* gears may allow a potentially a more efficient gear to realize its advantages.

- The higher-cost gears tend to harvest salmon in mixed stock fisheries, leading to suboptimal productivity of the combined stocks (Pearse, 1982, pp.47-57). The lower-cost gears tend to harvest in terminal fisheries that have fewer mixed -stock effects. Thus, if lower prices drive the higher cost gears from salmon fisheries, the wild salmon stock productivity could rise.

- Nonharvest fishing mortality is high for some gears. The salmon killed-to-landed ratio is 3 :2 for trolling and 5 :4 for gillnetting (Ricker, 1976, p.1485). Salmon traps can be designed to have a killed-to-landed ratio of close to 1 :1. Thus, if lower prices drive higher-cost gears from salmon fisheries, the wild salmon stock productivity could rise significantly.

(ii) As salmon prices fall, fishing pressures on the wild salmon stocks may decline, which should allow restrictions on the salmon fishing season to be relaxed, which, in turn, should decrease the farmed salmon market window (i.e. the period each year when fresh wild salmon is unavailable).

(iii) As salmon prices fall, communities dependent on the salmon fishery start to hurt financially. Governments often respond to such suffering by salmonid enhancement schemes and other forms of subsidization.

Given the above factors, it is likely that the region of decreased elasticity in the residual demand curve (i.e. between points A and B, Figure 3) will cover a large enough range of prices for the farmed salmon supply curve to intersect the residual demand curve at a point well above point B.

## 7. CONCLUSIONS

The burden of this paper has been to explore and explain the basic nature of the market interaction between the wild salmon fishery and salmon aquaculture, and thereby to speculate on the outcome of growing competition between the two sectors.

Their intrinsic economic structures are quite different, affording each sector a unique but different opportunity to access their joint market competitively. The lingering burden of common-use inefficiencies in the wild fishery has given it a reserve capacity to maintain market competitiveness by responding to salmon price reductions through rationalization. It may be speculated that the price-cost squeeze imposed on the wild salmon sector by expanding salmon aquaculture production will help to overcome inertia and remove political and social constraints against rationalization.

Salmon aquaculture owes its initial progress to technological success in producing at reasonable cost a commodity enjoying a high market value. It faces both advantages and disadvantages in its juxtaposition with the wild salmon fishery. On the one hand, competition from the wild salmon sector is held in check but the relatively fixed production capacity of that sector, which is constrained by the output limits of a natural system (as modified by limited enhancement possibilities). On the other hand, the staying capacity of the wild salmon sector is strong because of its reserve capacity to rationalize operations. This makes it difficult for aquaculture to capture market room from the wild salmon sector. As a result, the salmon farming industry will likely remain largely in the position of a residual market supplier. However, this still allows salmon aquaculture almost unlimited opportunities to expand through price reductions fueled by improved production efficiency.

5. *Competitive exclusion* (i.e. two species cannot both persist in the same niche) is a basic axiom of population ecology (Begon and Mortimer, 1986, pp. 76-80). Based on that axiom, two types of gear can only both persist in a fishery if they exploit different niches in the fishery or if regulation prevents one gear from excluding the other from the fishery.

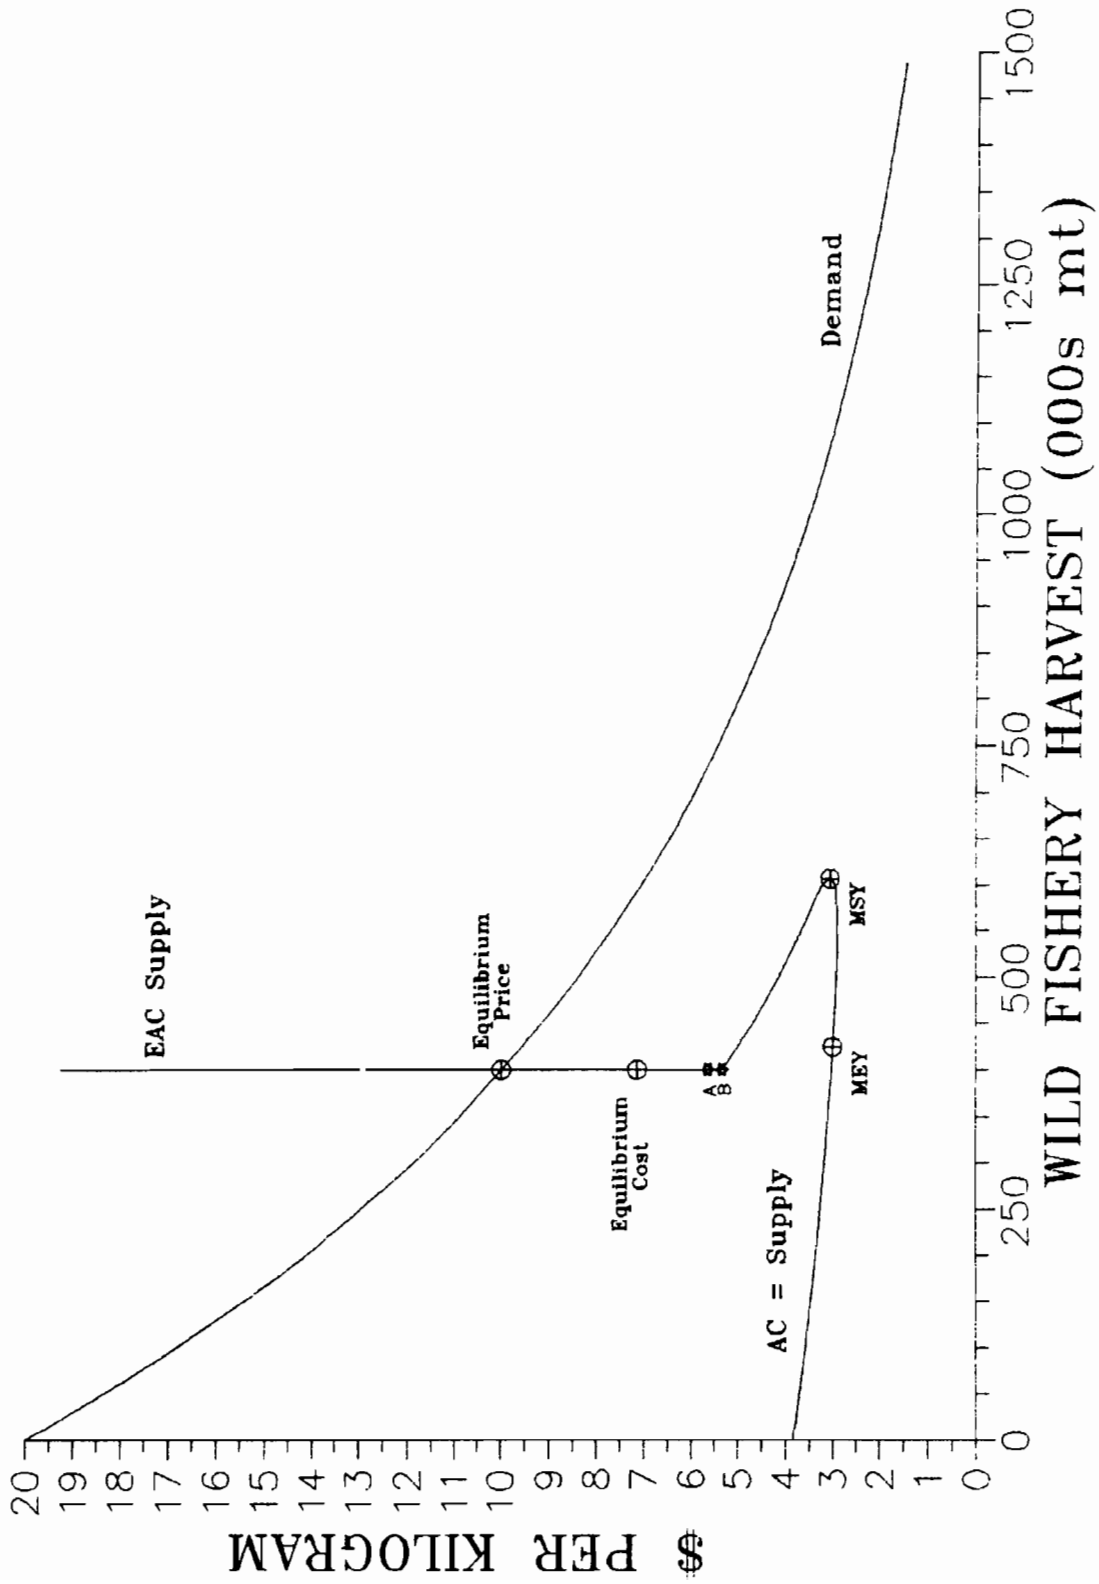

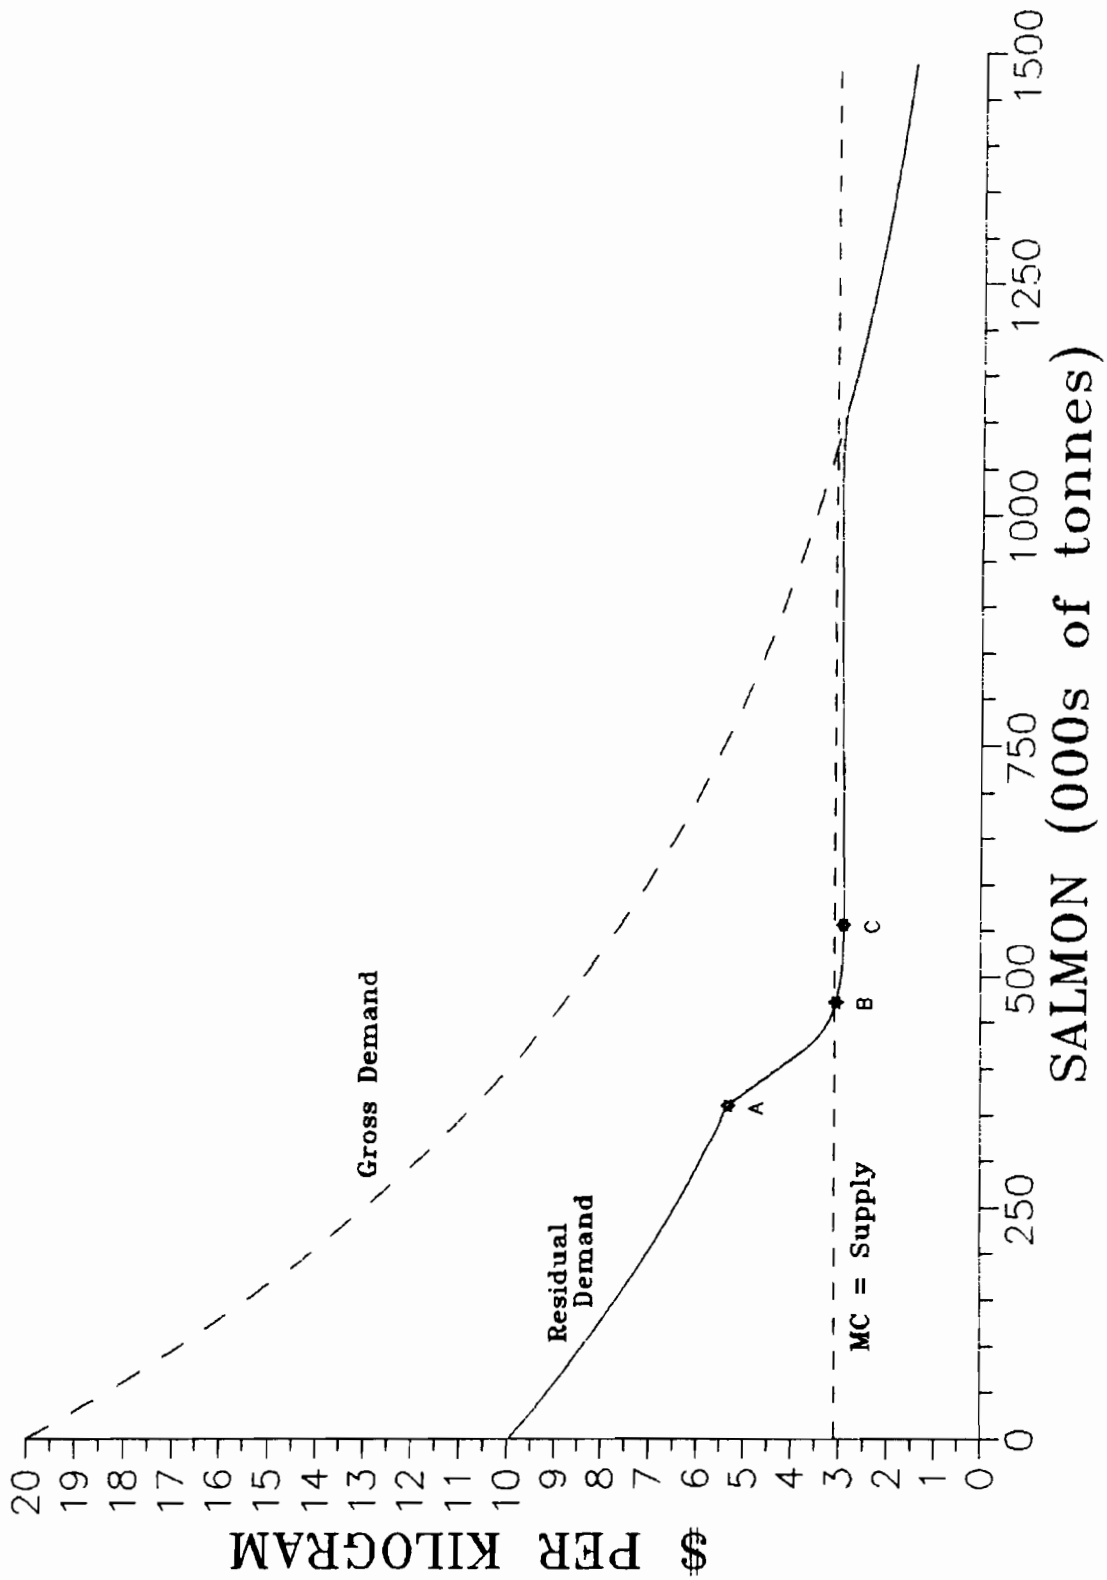

**FIG. 3.**
**THE FARMED SALMON MARKET — PERCEIVED AS BEING RESIDUAL TO THE WILD SALMON FISHERY.**

## A.1 THE WILD FISHERY

In keeping with a simple general model theme, the wild fishery is assumed to be a single stock, that is harvested by a single gear type, that behaves according to the Ricker (1975, pp. 282-283) model where the recruitement to the fishable stock is defined by :

$$R = aSe^{-\beta s} \tag{A1}$$

R = recruits (mt ; 2.5kg / piece
S = spawners = parent stock
$\alpha,\beta$ = parameters

The landed harvest is assumed to be a simple function of the fishing related mortality :

$$H = \delta qER \tag{A2}$$

H = landed harvest
$\delta$ = portion of M that is landed
M = annual harvest related fishing mortality
q = catchabilly coefficient
E = total effort

$$S = R - H / \delta \tag{A3}$$

The equilibrium spawning stock for any given level of fishing effort can be defined by substituting the RHS of (A2) into eqn (A3) and the RHS of eqn (A1) into that result :

$$\overline{S} = ln\,[\alpha(1-qE)] / \beta \tag{A4}$$

$$\overline{E} = ( 1 - e^{\beta s} / a ) / q \tag{A4a}$$

The equilibrium harvest for a given level of effort can be defined by sustituting the RHS of eqns (A1) and (A4) into eqn (A2) :

$$\overline{H} = ( \delta / \beta )\, ln\,[\alpha(1 - qE)] / [1 / (qE) - 1] \tag{A5}$$

$\overline{H}$ = escapment allowed catch (EAC)

which gives an equilibrium gross income in the wild fisheries of :

$$\overline{Y} = P( \delta / \beta )\, ln\,[\alpha(1 - qE)] / [1 / (qE) - 1] \tag{A6}$$

Most salmon fisheries are gauntlet fisheries and the *escapement* (nunber of spawners) is regulated to conserve the stock. Under those conditions, eqn (A4a) becomes :

$$\overline{E}^{\circ} = (1 - e^{\beta s^{\circ}} / \alpha) / q \tag{A4b}$$

$\overline{E}$ = target effort
$\overline{S}^{\circ}$ = target number of spawners

and eqns (A3) and (A1) can be combined and reorganized to define the regulated harvest :

$$\overline{H}^{\circ} = \delta S^{\circ}(\alpha e^{-\beta s^{\circ}} - 1) \tag{A7}$$

## A.2 WILD FISHERY : FISHING EFFORT AND FISHING COSTS

Fishing enterprises combine labour and capital on fishing vessel platforms to produce fishing power - the annual capacity to catch fish - the fishing season length then defines how much effort is applied to the fishery :

$$E = gmfV \tag{A8}$$

$$f = E / gmV \tag{A8a}$$

E = total fishing effort
f = fishinf power per vessel
g = effective fishing season length (part of a year)
V = number of fishing vessels
m = technology parameter

If the fishery managers control escapement then the fishing season is

$$g = \min\{E^{\circ} / (mfV) , g_n\} \tag{A8b}$$

$g_n$ = natural season length

## A.3 WILD FISHERY - FISHING COSTS

The following simple effort cost curve was designed with the idea that fishing inputs have both fixed and variable costs : [6]

$$C_F = V(\Phi + g\Omega)e[g^{.25}\tau f] \tag{A9}$$

$$C_{Fi} = (\Phi + g\Omega)e[g^{.25}\tau f] \tag{A9a}$$

$C_F$ = fishinf annual social cost
$C_{Fi}$ = fishing cost of vessel i
$\Phi$ = fixed cost of a fishing vessel
$\Omega$ = 0season related fixed cost of fishing power
$\tau$ = parameter reflecting economies or diseconomies of scale
e[n] = $e^n$

## B.1 SALMON FARMING : COSTS

DeVoretz et al. (1991b, pp. 3-4) provide a theoretical cost model for Norvegian farmed salmon :

$$AC_{SR} = ce^{hQ} / Q \tag{B1}$$

$AC_{SR}$ = short-run average production cost / kg
c,h = short-run parameters but long-run scale variables

$$MC_{SR} = che^{hQ} \tag{B2}$$

$MC_{SR}$ = short-run marginal production cost / kg

$$MC^{\circ}_{SR} = P = che^{hQ^{\circ}} \tag{B3}$$

$Q^{\circ}$ = output at which $P = MC_{SR}$

6. A more detailed discussion and model of these costs is provided by Wright (1991, pp. 76-77)

$$AC^{\circ} = P / (bQ^{\circ}) \tag{B4}$$

$$h = P / (AC^{\circ}Q^{\circ}) \tag{B5}$$

$$c = Pe^{-hQ^{\circ}} / h \tag{B6}$$

$$\pi_A^{\circ} = PQ^{\circ} - AC(Q^{\circ}) = P(Q^{\circ} - 1/h) \tag{B7}$$

The values that c and h take are determined by the current limits of technology. Salvanes (1988, pp. 91 and 109) provides a way to answer this empirical question (DeVoretz, et al., 1991b, p.1). If P is \$8.24, then :

$$AC = 3.05e^{(.067\ln^2 Q^{\circ} - .599\ln Q)} / 5.34 \tag{B8}$$

When eqn (B4) is set equal to eqn (B8) the result can be reorganized to :

$$c = 5.34P / [3.05e^{(.067\ln^2 Q^{\circ} - .599\ln Q)}] \tag{B9}$$

Equation (B5) can be reorganized to :

$$Q^{\circ} = (\ln [P] - \ln [ch]) / h \tag{B10}$$

The output at which (for a scale of operations – values of c and h) the average cost is minimized can be defined by differentiating eqn (B1) with respect to Q, setting that result equal to nil and reorganizing it to :

$$Q^* = 1 / h \tag{B11}$$

Figure B1 is adapted from DeVoretz et al. (1991b, p. 10) to show what eqns (B1) through (B4) look like when Q* is at the global minimum AC.

Figure B2 is adapted from DeVoretz et al. (1991b, p. 12) to illustrate the long-run AC envelope. Based on the DeVoretz et al. (1991b) values, if :

$$h = 1 / Q^* = 8.707E4 \tag{B12}$$

$$c = P^*Q^*e^{-1} = 1.3029E{-}5 \tag{B13}$$

then :

$$Q^* = 76{,}749 \text{ kg} \tag{B14}$$

$$P^* = MC^* = AC^* = \$3.0838 / \text{kg} \tag{B15}$$

and, in the very long-run, eqn (B15) is the aquaculture supply curve. Howewer, while there is rent available to salmon farms (in the short to intermediate-run) frams will supply salmon based on eqn (B3). If rent is available for a long time, the long-run supply function of a typical salmon farm can be defined by adjusting (for a range of salmon prices) parameter c until the values produced by eqns (B9), (B10) maximize the farm's profit - eqn (B7).

# Determinants of Price in the Portland, Maine Fish Auction

**Nida Ty and John M. Gates**

Department of Resource Economics, The University of Rhode Island, Kingston, RI 02881-1630, USA

ABSTRACT

*The Portland fish exchange is an unusual fish market in North America. Fish are segregated by species, size and vessel into lots of up to about 1200 pounds. Fish buyers are able to inspect each lot in advance of the auction. This structure permitted a stratified random design to elicit buyers evaluation of fish quality using standard quality criteria in Food Science but modified on the advice of a panel of buyers. The questionnaire was distributed to buyers on randomly chosen days in July, 1990 for lots of codfish (the largest volume species) chosen randomly but stratified by size category. A panel of buyers agreed to score the quality of these lots using a pretested questionnaire. The results were collated with their transaction prices and other pertinent data such as lot size, total volume on the exchange that day, and buyer characteristics. These data were analyzed using multivariate regression methods to determine the effects of measured variables on the exchange price of each lot. Because each observation involves a known, homogeneous quantity and quality of fish, the data are much more precise than is often the case with fisheries market data. The Portland Fish Exchange is, to all appearances, a reasonable approximation to a purely competitive market, the behavior of buyers is believed to yield good estimates of true market preferences. The results indicate significant price differences with respect to fish size, (some) quality measures, lot size, harvesting technology and fishing grounds. At this time, the results are being discussed with an industry panel to ensure that our interpretations are plausible and not simply statistical quirks. This study does not shed light on the larger question of what would happen if all fish markets were to increase fish quality ; to claim otherwise would be a fallacy of composition.*

## 1. INTRODUCTION

This paper summarizes a study of quality factors affecting fish prices at the open-display auction market in Portland, Maine. Although similar markets exist elsewhere in the world, this one is unique in the United States. Fish quality attributes deemed important by the fish buyers were identified and their effects on bid prices at the Portland auction

market were measured. Cod was chosen as the target species because it ranks among the top five species in terms of consigned weight and value at the Portland fish auction market and is one of the most abundant and commercially important groundfish in the Northeast region.

## 2. BACKGROUND INFORMATION

A literature review and discussion of "Hedonic Price (HP)" models is contained in an appendix available from the authors.

An auction is "a market institution with an explicit set of rules determining resource allocation and prices on the basis of bids from the market participants" (McAfee and McMillan 1987). Cassady (1967) regarded auctions as an essential marketing device for fresh fish, the price of which is dominated by current supply and demand conditions. Proponents of the auction system for marketing fish such as Nichols *et al.* (1980) maintain that auctions, in general, provide high prices to the fishermen and high quality products to the consumers.

### *2.1 The Portland Fish Exchange* (PFE)

PFE opened in May of 1986 to manage the only all-display fresh fish auction market in the United States. The PFE was premised on the idea that an open marketplace can act as a price-setting mechanism which is fair, accurate, and responsive to product quality. The PFE auctions take place at 1 p.m. on Mondays through Thursdays and 11 a.m. on Sundays. Prior to auction time, the buyers and sellers' representatives receive a "detail" sheet which resembles an auction board listing of species, size classes, date, lot number, boat number and name, and weight. The order of the auction is by species by cull (size). The average running time of one auction round is an hour. Fish are auctioned off using the English (ascending-bid) system. The top bidder chooses "one or all" of the pallets of fish of a cull just bid. A 12,000-pound limit is set to avoid having only one buyer buy all the fish of particular species and cull without giving a second chance to other buyers. If more than ten pallets is desired, the buyer has to continue to bid for additional fish and to succeed must be the top bidder each time. The minimum purchase for each bid is one lot, which may be less than 900 pounds on partial lots. The bidding starts all over if there is more of that cull of that species after the first top bidder has chosen his lots. After the last species and cull have been auctioned off, buyers are allowed a second period of bidding on any items that were not bid on during the original auction. This round lasts for about five to ten minutes only. A seller has the right to refuse or "scratch" the sale (by saying "no sale !") at the time a given species by cull is being auctioned. Any scratched sale allows the buyer one final rebid of any amount. If the sale is still scratched after the rebid, the seller may either leave the scratched lot for next day's auction or remove it from the auction floor. The same options are available for lots which did not receive any bid at all.

This brief characterization is in stark contrast to the auctions at Boston and New Bedford where fish are bid upon without prior inspection by the buyer ("sight unseen"). Further information on these other fish auctions in new England is contained in an appendix available from the authors.

Buying fish sight unseen in the Boston and New Bedford auction markets has caused several problems for both buyers and sellers. Among the complaints aired are price-fixing, cartels, dishonest weights, and back door deals. Buyers have to rely on indirect measures of the fish quality such as the reputation of individual captains, the length of their trips, gear used, catching grounds, and other information. In an all-display fish auction market, as in the PFE, buyers can visually inspect the fish before bidding. The bidding among the buyers allegedly establishes premiums as well as discounts in relation to the product's quality attributes. Even if quality differentials are not revealed automatically, competitive auctions provide a "melting place for buyers and sellers who would benefit from markets for higher quality products" (Peterson and Georgianna 1988).

### *2.2 Price-Level Comparisons*

Conventional wisdom in the New England fishery market holds that the fresh cod, haddock, and pollock round ex-vessel prices are set in the Boston auction. A visual comparison of the Portland and Boston cod prices appears in Figure 1 for

the years 1985-1989. As shown in Figure 1, the price level and gap are compared between the pre-PFE (before June 1986) and the post-PFE (after June 1986) periods. The Portland prices increased from an average of 51.4 cents per pound to 68.9 cents per pound or a 34 percent price jump between the two periods. The Portland average prices were 24.5 percent lower than the Boston prices before PFE opened in June 1986. In the post-PFE period, the Portland prices were only 14.4 percent lower than Boston prices. Using a t-test of difference between means, it was found that the price gap between the Portland and Boston ports has significantly narrowed during the period. The equilibrium price difference between spatially separated competitive markets such as Boston and Portland is the transport cost between them. There has not been much change in the transport cost between these regions ; the narrowing of the Boston- Portland price gap is inferred to have been effected by enhanced competition and better quality of fish landed at the PFE.

## 3. RESEARCH METHODS

Sensory evaluation of fish quality required a panel of "judges". Six fish buyers were chosen on the basis of their experience and reputation as quality-conscious buyers at the auction. Since this study was done at the primary market or first exchange level, only quality characteristics of raw whole fish were measured. After consultation with the panel evaluation members and with food scientists, various parts of the fish were chosen as units of assessment for the quality attributes related to appearance, texture, color, and odor. The flesh is assessed for its firmness or consistency. The fish's skin is examined to note any loose scales and discoloration or bleaching of certain areas. The appearance of the eyes is a good guide to degree of spoilage. Very fresh fish have bright, convex or bulging eyes with a dark pupil. As spoilage proceeds, the eyes turn duller and grayer and become flat, then concave or sunken. In general, off-odors can be detected first in the area around the abdominal cavity. That is because the intestines and the gut cavity of the fish harbor large numbers of spoilage microorganisms and autolytic enzymes (Huss 1988 ; Connell 1980).

The volume of cod landings at PFE vary seasonally with a peak in May or June and trough in January or February. The month of June was purposively sampled as representative of a peak cod-fishing month. Nine auction days within the month of June were randomly selected, spread across from the first to the fourth week. The panel evaluations of cod lots were conducted during the period June 5-21, 1990. Systematic sampling was used to pick the lots for each day. All the large-sized lots were evaluated since the total number of lots under this category rarely exceeded 20. A total of 440 cod lots were sampled for sensory evaluation. Eleven (11) lots, however, did not receive any bid and were removed from the auction floor by their sellers. Assigning zero values for the sale price variable in these cases is unrealistic since these lots would command positive prices if sold in other markets. Consequently, these cases of missing values were dropped which resulted in a final sample size n = 429 lots of cod fish. Buyer inspections of the cod lots were usually done one or two hours before auction time. Each of the judges evaluated the randomly chosen lots independently of the other evaluators. One or two fish are picked from each box within an individual lot. The evaluator held each fish and examined closely the flesh, skin, and the eyes. Then each fish was smelled by bringing it close to the nose comparing the odor with the description on the scoresheet.

For the study, the HP model for cod was specified as :

$$P_i = P( Z_1,..., Z_j, D_1,..., D_k, e_i ) \quad (1)$$

where P or Price is either the actual auction sale price, PR, or a relative price measure, PP, for lot i. The Z's measure the physical quality attributes which were assessed through various parts of the fish for each lot. The D's are non-physical but quality-related attributes representing gear type and fishing grounds and $e_i$ is a stochastic error term.

The auction sale price (PR) represents the actual price paid by the highest bidder for one or more lots (up to maximum of 10 lots) on a given round of bidding. In cases of "scratched" or "no sale" lots, the highest bid is treated as the sale price, even if sale was refused.

An alternative price variable is the percentage price (PP) which is a relative price measure. It is the ratio of the actual sale price (PR) and the average daily auction price for each size category for a given day. By expressing the actual prices received for cod lots as percentages of a daily average price quotation, the influence of supply on price was reduced. In this way, it is possible to arrive at some measure of the average influence of certain quality factors on prices which may be above or below the average market price.

Apart from size and lot weight, all the other physical quality attributes were scored before the auction by the participating buyers. Each part of the fish was scored on a 0 (least acceptable) to 3 (most acceptable) scale. Category scale data are usually considered to be at least ordinal level data. They do not generally provide cardinal measures of value. Thus, on a category scale for odor quality, a product rated a 2 is not necessarily twice as good as a product with a score of 1. It can be noted, however, that there is an underlying continuum being approximated by artificial categories. For example, in the odor scale where 1 is "slight off-odor" and 2 is "trace of off-odor", there is a range of odor types between these two discrete numbers not accounted for by the scale. Only a very sophisticated measuring instrument can reveal the underlying interval scale. In the statistical analysis, all the quality score variables are treated as continuous interval variables. Scores for each part inspected by the four evaluators are averaged.

A higher score for each part inspected signifies better quality grade. The coefficients of the four score variables (FL, SK, EY, and OD) should all be positive since higher values for these variables represent higher grades and price should increase as grade improves.

The bruising characteristic (BR) is measured by a discrete qualitative variable where 0 denotes absence of bruising and 1 means presence of bruising. A price discount, hence a negative coefficient, is expected for this variable.

The only institutionalized grading at the PFE is size grading. This is done visually and manually with the aid of a weighing scale. For size sorting, the size categories follow the PFE cull standards which is as follows : Scrod (or small) cod, which has to be at least 19" long, weighs between 1.5 to 3.5 pounds ; market cod is from 3.5 to 10 pounds ; and large cod is anywhere over 10 pounds in weight. When available, cod weighing more than 22 pounds are classified as "whale" cod. Large fish of a given species generally command the highest prices. The coefficients of the size categorical variables (SZL and SZM) are hypothesized to have positive sign.

It is a common notion that fish buyers like to buy big lots. Other things being equal, a full lot is preferable to a partial lot. Therefore a positive coefficient for the lot weight variable (WT) is expected.

Two qualitative variables representing the gear type and the fishing ground of the boat-suppliers were analyzed. These variables are hypothesized to be important determinants of the value of cod. Gears were classified under two categories : the otter trawl and the gillnet types. The expected sign of the coefficients of the gear type and the fishing ground dummy variables is not definitely known. This is because although fish caught by gillnetters were thought to be of better quality (suggesting a negative coefficient for otter trawl qualitative variable), otter trawlers have been upgrading methods of handling and preserving their catch and have improved the quality of the fish they land (suggesting a positive coefficient for otter trawl dummy). Fishing ground was either offshore (o) or inshore (i). Fish caught from inshore fishing grounds may or may not be better than those from offshore grounds in terms of physical characteristics, even if some consumers maintain that inshore fish taste better.

Generally, any system of price premia and penalties can change with changing supply conditions (Waugh, 1929). To account for day-to-day supply fluctuations during the study period, a quantity consigned variable (QC) was used.

A list and description of all the variables discussed above is shown in Appendix A. They are grouped into categories described by equation 1.

Using the Student's t-test, one can determine if an attribute is an important determinant of the cod price. However, sequential application of the t-test to multiple characteristics within the same sample is not valid since statistical independence is violated.

## 4. ESTIMATION RESULTS

Five alternative functional forms, (linear, log-linear, semilog, inverse semilog, and quadratic) were examined. Several criteria were considered in choosing the final model. The first is consistency of expected signs and magnitudes for the coefficients of the explanatory variables. Then the goodness of fit of the regression equation is evaluated and reliance is placed on the F-statistic which tests the joint hypothesis that all coefficients are zero. To detect multicollinearity, the condition number and the values of the proportions of the coefficient variance were examined. Finally, the residual patterns were examined to see if residuals had patterns or tended to occur randomly. Autocorrelation in the the price variable was examined using the Durbin-Watson (DW) test.

The semi-log model gave the best results in terms of expected signs, magnitude of coefficient values, t-statistics of estimated parameters, condition number, and goodness of fit. Analysis of the residuals using plots and regressions against the explanatory variables did not suggest a significant problem of heteroskedasticity. Serious multicollinearity was not present as evident from a low condition number (equal to 17.45). The Durbin-Watson statistics for autocorrelation were in the inconclusive regions with $d_l < DW < d_u$. Results of the final set of OLS regressions appear in Table 1. The results from semi-log estimation using percentage price (PP) as dependent variable are provided for comparison.

Except for the skin score variable (SK), all the signs of the estimated coefficients were consistent with expectations. Seven (7) out of the total of 11 coefficients have coefficient :standard error ratios in excess of 1.7. Quite unexpectedly, the variables eye score (EY), skin score (SK), and bruising (BR) were not significant determinants of price variation. The coefficients of the skin and eyes score variables consistently showed low t-values and high standard errors in all the functional forms examined. A singular value decomposition was performed which suggested that multicollinearity among the score variables did not appear to be the culprit.

The standard partial regression coefficients, also called beta coefficients are computed from the parameter estimates of the semilog model. For the ith beta coefficient, i = 1, 2,..., k,

$$BC_i = b_i (S_i/S_y) \quad (2)$$

where $b_i$ is the estimated regression coefficient, $S_i$ is the standard deviation of the ith explanatory variable, and $S_y$ is the standard deviation of the dependent variable which is price in this model. As a unitless measure, each of the $BC_i$'s measures the direction and number of standard deviations that price changes for each one standard deviation increase in the explanatory variable. The absolute value of a beta coefficient is indicative of the degree of influence or relative importance of its associated variable on price. The magnitude of the price effect is computed for each standard deviation change in the explanatory variable. Table 2 includes only those variables with estimated coefficients significant at the 5 percent level or better (one-tailed test). The price effect estimates for the dummy categorical variables are interpreted in relation to the reference category.

The size characteristic was the strongest determinant of price. On average, lots in the market size category receive 13.35 cents per pound more than those in the scrod category while those in the large category receive 33.44 cents more than scrod-sized lots.

Examination of the quality score data suggested that the flesh, skin, eyes, and odor scores were all intercorrelated with simple correlation coefficients ranging from 0.37 to 0.58. An alternative measure for adjusting the model would have been to construct a composite quality score variable. This would have required, however, a method of assigning weights to the four rated parts and was deemed to be arbitrary. As it turned out, the flesh and odor quality scores showed significant t-values at the 1 percent level. Discussions with some fish buyers knowledgeable in fish quality and fish processing suggested that fish buyers are more sensitive to flesh and odor conditions than to condition of the skin and the eyes. Food technology experts have, often times, also chosen flesh texture and odor as quality attributes to be rated in conducting sensory evaluations of fish products.

As expected, the coefficient for lot weight has a positive sign perhaps because unit transaction costs are diminished as lot size increases. Fish landed by otter trawls receive a premium of 2.47 cents per pound in comparison with fish landed by gillnetters. This can be indicative of the improvement in the methods of catch storage and handling among trawler-boats. The flesh, skin, and odor condition of trawled catch were found to be significantly better that those of the gillnetted catch. This result was unexpected. However, a meeting at PFE, buyers were not surprised. They attributed the result to the anatomy of cod for which the most valuable cuts are vulnerable to gillnet damage. They felt that this result would not hold for other species and perhaps not for other seasons.

The quantity consigned variable was included to isolate the effect on price of daily supply variability. The magnitude of the quantity effect on price can be considered only within the range of values included in the data. Due to the wide variability of catch levels from month to month and from year to year, it is not possible to infer results for other seasons from this sample which focused on the peak supply month.

## 5. SUMMARY AND CONCLUSIONS

On the basis of several criteria, the overall explanatory power of the final model was considered quite acceptable. Seven out of the eleven coefficients in the regression equation were much larger than their standard errors and accounted for 72 percent of the cod price variation over the period of study. The residual variance can be partially attributed to the fact that buyers possess market information which may not be related to quality factors or local (PFE) supply conditions.

The results indicate that fish buyers take advantage of the open display feature of the Portland auction market to examine other physical quality characteristics deemed important to assure freshness of the fish lot they are bidding for. Physical characteristics pertaining to size, flesh condition, odor and lot weight are important considerations for the fish buyers at the Portland fish auction market. The premium differentials arising from other quality factors related to texture, color, and odor seem insignificant, in practical terms although they they are significant in statistical terms, compared to size-related premiums.

If the magnitudes of the price impacts are meaningful, then these values can provide important informational inputs in the decision-making process of the fishermen, processors, and policy-makers. To some extent, producers have substantial influence on the size mix of their catch through their gear type and/or mesh size decisions. Moreover, selection of methods of handling and preserving the catch on board may be the best way that producers have of affecting the flesh and odor conditions of landed fish. Once the relative values of the quality attributes are known, producers are provided with estimates of the possible value gains to be had from certain actions, thereby enabling reliable estimates of cost-effectiveness or cost-benefit to be made.

The efficient performance of the Portland Fish exchange, especially in its size-grading function, has resulted in some payoffs. The current sorting system which is based solely on size was found to explain 62 percent of the variation in cod prices. The important role played by the open-display type of fish auction is undeniable. As competition among buyers for high-quality fish intensifies, a fair and accurate system of pricing will eventually prevail and Portland could emerge as the price leader in the fresh fish market of the region. Where price premia exist for high-quality fish, fishermen have the economic incentive to improve quality. Market based standards of quality would diminish the need for mandatory federal inspection for the fishing industry.

COD PRICES-JAN., 1985–DEC., 1990 PORTLAND & BOSTON.

Appendix A. Descriptions of Variables in the Hedonic Price Model for Cod

| Variable | | Definition |
|---|---|---|
| Price | | |
| PR | = | Auction sale price in cents per pound of cod for lot i |
| PP | = | Percentage price which is the ratio of the auction sale price for lot i and the average price of cod for that day |
| $z_j$ | | |
| FL | = | Flesh score [a] |
| FL | = | Skin score [a] |
| EY | = | Eyes score [a] |
| OD | = | Abdominal odor score [a] |
| BR | = | Dummy variable for bruising, where BR = 1 if bruising is present, BR = 0 if bruising is absent. |
| SZ | = | Categorical variable for size or cull, where SZL = 1 if size is large, SZM = 1 if size is market, and SZS = 1 if size is srod (reference category) |
| WT | = | Lot weight of dressed/gilled cod (in pounds) |
| $D_k$ | | |
| GR | = | Categorical variable for the boat's gear type, where OTR = 1 if gear type otter trawl and NET = 1 if gear is gillnet (reference category) |
| FG | = | Categorical variable for fishing ground, where IN = 1 if inshore and OFF = 1 if offshore (reference category). |

[a] Scores are averaged across evaluators.

## Appendix B. Conceptual Framework : Hedonic Prices and Product Characteristics

Waugh (1929) criticized economic theories of value for the neglect of "quality factors which determine whether the particular sale in question will be made at prices above or below [the] general level". Since that time several theories dealing directly with quality evolved. Most of the earlier works is in the hedonic price (HP) index literature, the earliest of which dates back to Court's paper in 1939. Adelman and Griliches (1961) proposed that "the quality of a commodity is a composite of different characteristics". Lancaster (1966a, 1971) did a pioneering work on the characteristics approach to consumer demand. Lancaster's theory is that utility or satisfaction is derived from the properties or characteristics which goods possess rather than goods themselves. Lancaster asserted that the relevant characteristics should be defined not in terms of people's reaction to the good, but rather in terms of objective measurement. Thus, to Lancaster, a characteristic must be defined in terms of properties of the good itself, such as calorie content of food or cooling power of an air conditioner. Lucas (1975) formulated a HP function as a regression of the observed price of a commodity against its quality attributes. The underlying hedonic hypothesis states that goods are valued for their utility-bearing characteristics and that the prices of goods vary directly with the specific amounts of each characteristic the product contains. The observed product prices are viewed as a composite of the values of the product's characteristics. A generalized HP equation is a regression of the form :

$$P_i = P ( V_{i1} ,..., V_{iJ}, u_i )$$

where $P_i$ is the observed price of the commodity i, $V_{ij}$, j = 1,..., J measures the amount of some "intrinsic quality" per unit of commodity i, and $u_i$ is a stochastic error term. The partial derivative with respect to any of the characteristics is the HP or the implicit marginal price of that characteristic. According to Rosen (1974), an estimated HP function does not typically identify a supply or a demand function since it is defined only over the characteristic space and its arguments consist exclusively of characteristics.

Early applications of HP methods involved the value of quality change in consumer goods or of quality in price indices (Adelman and Griliches 1961 ; Griliches 1971). Rosen (1974) used the HP concept to analyze the supply and demand of the characteristics which differentiate products in competitive markets. These studies were based on the idea that variations in the prices of different brands or models of a product reflect differences in the amount of certain basic attributes that they possess. Most of the early empirical applications have dealt with industrial products such as consumer capital goods such as automobiles and electrical apparatus. Hedonic values of residential property have been used to measure environmental benefits.

In the agricultural sector, hedonic studies were done to explain variations in prices of cotton and deer hunting leases and more recently for rough rice bid/acceptance markets (Brorsen *et al.* 1984), beef carcass auction markets (Porter and Todd 1985), and lamb carcass whosesale market (O'Connell 1986). The hedonic study of rough rice by Brorsen *et al.* (1984) led to identification of quality factors such as head yield, mill yield, and test weight which are also important in determining rice's value. These factors are not included in the present system of establishing federal grades for rough rice. In his hedonic model of the Paris lamb carcass market in Paris, France, O'Connell extended the price equation to include country of origin, which is a non-quality attribute. The results showed that supplying countries aside from France "suffer a substantial country-of-origin discount which is not justified on quality considerations". Porter and Todd's model of the beef carcass auction markets in Perth, Australia identified eight quality factors which significantly affect beef prices. Five of these factors, namely ; meat color, fat color, trim, length, and grain feeding, were suggested to be included in the Australian carcass classification system.

# The Price Equalization Fund of the Fisheries in Iceland A Descriptive Study

**Olafur Örn Klemensson**

Central Bank of Iceland

ABSTRACT

*The objective of this paper is to illuminate and discuss the system of stabilizing the export prices of the fisheries' sector. The paper is divided into five sections. In the first section, it is be shown how important the fisheries are for the Icelandic economy. In the second section the rational behind efforts to reduce economic fluctuation caused by changes in export prices of the fisheries' sector is discussed. Thirdly the price development of the main fish products is shown. Next the main features of the Price Equalization Fund, its implementation and how it works are described and in the fifth section, the experience of the price equalization policy is discussed including how it can contribute to the stabilization of the economy.*

## 1. THE IMPORTANCE OF THE FISHERIES' SECTOR

The Fisheries' sector is of fundamental importance to the Icelandic economy, as it has been for most of this century. Fish products account for more than 75% of the merchandise exported, contributes directly 17% of the GDP and employes 13% of the workforce. This fundamental role of the fisheries on the economic development can be seen in Fig. 1.

With a simple regression it can also be shown that 75% of the total variation in the growth rate of the GDP can be explained by these factors.

The equation is:

DGDP 0.23*DCATCH + 0.13*DCATCH(-1) + 0.10*DTOT + 0.18*DTOT(-1) + 0.077*DTOT(-2) + 066*DUMMY1971*0.030

(4.33) (2.46) (1.75) (3.56) (1.39) (2.63) (7.07)

These facts make the Icelandic economy unique in comparison with other European countries. The size and importance of the fisheries' sector put Iceland among the few countries of the world where fisheries are the pillar of monetary and fiscal system.

The Icelandic economy has been relatively unstable as shown in Fig.2. The main reasons for this volatility are the annual changes in the catch of the main fish species and fluctuations in the price level on fish products of foreign markets. The economy is very open through its high dependency on foreign trade which accounts for some 35% of GDP. All these facts makes the economy highly exposed to exogenous factors.

It must be one of the prime objectives of any government to reduce fluctuations in economic activity and thus diminish uncertainty and instability in the economy. It is not in the power of Icelandic authorities to influence developments outside the Icelandic economy such as fluctuations in the price level of fish products, but it is possible to reduce adverse effects of these fluctuations on other factors of the economy. With the right economic policy mix it ought to be possible to adjust the economic development toward more stability, reduced inflation and make the way for continuous economic growth.

It has been shown above that there is an overwhelming influence which the fisheries' sector has on the economic performance in Iceland. All major fluctuations in the economic activity have been caused by changes in the output or in the export prices of the fisheries' sector. To illuminate this a typical business cycle in Iceland can be described as follow.

The upswing usually begins with either increases in fish catches or in price level of fish products or even both at the same time. This leads to a rise in income, first within the fisheries' sector, but then also in other sectors as most of the increases in income within the fisheries' sector will spill over to other sectors. The overall level of demand then rises and the demand for labour will push up the rate of real income. The net result on the fishery industry is that only a marginal part of the higher income is retained within the fisheries' sector as most of it flows to other sectors as has been described. In the meantime the higher level of demand and money supply has led to a demand-induced inflation, and production costs increase accordingly. With subsequent decline in export prices or in the fish catch, the firms in the fisheries' sector must face a higher level of production costs but at a lower level of income. These firms have serious difficulties adjusting to the adverse effects of lower prices and higher productions costs. This usually induces great pressure on the exchange rate which ultimately leads to devaluation of the currency.

This model describes exactly what happened in the years 1986-1990. The price level of most fish products began to move upwards in the second half of 1986 and continued on till the peak was reached in late 1987. The catch was rather good in these years as were other factors affecting the fisheries. As has been described above, the higher level of income in the fisheries' sector led to higher costs and, ultimately, a much higher level of real income the other sectors of the economy. This resulted in a sharp rise in the real exchange rate of the currency and very serious difficulties within the fisheries' sector. In spite of greatly increased turnover an higher net income, most of the fishery businesses were not able to build up reserves during this period of two very favourable years. The adjustment process was a very difficult and a costly one. The currency had to be devaluated and this led to higher inflation and the Government had to write out state-guaranteed loans on a big scale, and at least some of them, eventually, must be redeemed by the state.

This experience led to renewed discussion about a new and more effective price equalization fund to replace an older fund which had been established in 1969.

## 2. THE NECESSITY OF ECONOMIC STABILITY

In Iceland it has been the prime objective of the economic policy to reduce the inherent instability of the economy. The core of the stabilization policy is to slow down the expansion by withholding a part of the excessive monetary supply. Theoretically it can be accomplished with either general policy tools, like fiscal, monetary or exchange rate policy or with selective methods like the price equalization scheme i.e. withholding part of the income of the dominant sectors of the economy.

There is a good cause to believe that fiscal and monetary policy methods are too general to be sufficient to ensure stability in the Icelandic economy. Other policy methods, more selective, should be of great help in the stabilization process.

Changes in the exchange rate of the Icelandic Króna have often been used in the past to secure the competitiveness of the fishery industry but the experience indicates that a stable exchange rate is a prerequisite to bring forth moderate wage agreements and low inflation.

The economies of Europe are in a transition towards a more unified economic system and Iceland will be a part of the EEA agreement as from 1993. This transition to economic unification will dramatically reduce the policy alternatives at hand. Closer economic ties will also make it imperative to increase stability in the economy.

This development will greatly restrict the possibilities of the monetary authorities to use a discretionary exchange rate or monetary policy to stabilise the fluctuations. This tighter economic co-operation also calls for more stability in the Icelandic economy and the same overall economic performance as per European standards.

This development can be used to point out the necessity of using custom made policy tools for the implementation of the stabilisation policy.

Two other arguments for the case of an active price equalization scheme have been brought forward. The first argument is built on the assumption that it is necessary to ensure equity between the competing economic sectors by letting the dominant fisheries sector take part in an obligatory saving scheme in the form of a price equalization fund. The second argument rests on the usefulness for the businesses in the fisheries' sector in building up reserves to meet unforeseen fluctuations in income caused by changes in export prices.

## 3. PRICE DEVELOPMENT OF MAIN THE FISH PRODUCTS

To illustrate the effects of the price fluctuations of fish products on the economic development, it is helpful to draw up graphically the price development of the main fish products during the past 20 years.

In Fig. 3.a) the prices of groundfish products and fish meal and oil are plotted for the period 1964-1991 and in Fig. 3.b) the prices of crustaceans are shown, calculated in SDR at current and fixed prices.

The price fluctuations are distinctly different between fish products. The price of frozen fish has been relatively stable compared with the price of fresh and salted fish. Fish meal and oil prices are the most unstable of all fisheries products.

The intensity of the fluctuations have been evaluated with help of standard deviation of changes between yearly averages of fixed prices in SDR.

Standard deviation of yearly changes in SDR-prices

| | |
|---|---|
| Frozen fish | 7.6% |
| Fresh fish | 18.3% |
| Lobster | 13.4% |
| Shrimps | 16.5% |
| Scallops | 19.5% |
| Salted fish | 18.7% |
| Fish meal and oil | 22.9% |

## 4. THE PRICE EQUALIZATION FUND

### *4.1 New Legislation*

The old Price Equalization Fund of the Fishery Industry from 1969 had been only partly active for some years as the main activity was limited to crustacean species and salted fish. The Fund had deliberatly been put out of action regarding frozen fish products during the years of very high prices, i.e. between 1986-1988.

The role and usefulness of price equalization of the export prices of fish products was very much in debate during the drastic fall in prices during 1988 and 1989. The general consensus was that only two alternatives were possible: to abandon totally the idea of stabilazing the prices of fish products and to improve the price stabilization system.

After prolonged discussion, a government-appointed committee of politicians and representatives from the interested groups came out with a proposal for a new and improved price equalization fund in spring 1990.

In May 1990 the Parliament passed a law on the new Price Equalization Fund of the Fisheries (P.E.F.).

### *4.2 The Characteristics of the New Fund*

The main characteristics of the P.E.F. are the following.

i) The main purpose of the Fund is to diminish the effects of fluctuation in prices of fish products on the economy.

ii) According the new law the price equalization is to cover all fish products exported from Iceland.

iii) The fund is divided into sections according to the lines that divide the Icelandic fisheries sector: these are the sections for processed and unprocessed groundfish; sections for lobster, shrimps and scallops; the section for fishmeal and oil and the section for herring.

iv) Payments into the Fund are treaded as taxes. Inpayments are therefore not direct property of the fisheries companies concerned. The companies are only entitled to compensation payments (outpayments) when the prices fall.

v) The accrued capital of the Fund must be invested outside Iceland, which is necessary to ensure the targetted economic effects.

vi) Participation in the Fund is obligatory but all companies taking part in the Fund have an individual account in each of the seven sections of the Fund. Inpayments of duties are therefore earmarked the individual company. Outpayments to compensate for any fall in prices are restricted to the amount which each company has on its individual account at the Fund.

To achieve the objectives of the Fund, the following prerequisites have to be met.

i) The implementation must be as simple and transparent as possible. All calculation will be made at the office of the P.E.F. on the basis of information retrieved from the exporters. The proportional inpayments and outpayments are on a monthly basis and will be announced several days before they take effect. It is therefore known to all subjects concerned some days in advance what the proportion of inpayments and outpayments will be.

ii) To restrict the function of the Fund to smooth out fluctuation in prices but not to take into account other factors such as volume of catch or net business results in the fisheries' sector.

iii) The functioning must be as self regulating as possible with a minimal number of parameters to decide upon.

### *4.3 The Formulas for Calculation*

The main function of the price equalization scheme is to levy percentage duties on fish products when the marked price is over a certain average and pay out compensation when the actual marked price is under the calculated average.

In detail, the features of the system are as follows.

The calculation of price equalization is kept very simple. The law of the Fund prescribes precise rules for deciding in-or outpayments.

The Board of the Fund has five members, three of whom are directly appointed by the Minister of Fisheries and the other two being appointed after suggestions from shipowners, fishermen unions and the processors. It means that the Minister

always has the majority on the Board. The Board has to decide the percentage of inpayments or outpayments of the export value in each of the seven sections. The percentages are to be decided for each month in advance. The decisions of the Board must be publicly announced.

The calculation is made in several steps. First, for every month the average marked price for the products in each of seven sections of the Fund must be calculated, the necessary information being retrieved from the producers. In the second step the marked price is then adjusted for inflation (CPI indices for the five biggest industrial countries in OECD). The third step is to calculate the so called basic price, i.e. 60 months moving average price for each of the sections. The final step is to calculate the proportional difference between the inflation-adjusted marked price and the basic price. If the difference is positive the producers must make inpayments to the Fund and if the difference is negative the Fund has to pay compensation to the producers. The formulas behind the calculations are shown in Appendix 1.

## 5. THE EXPERIENCE OF PRICE EQUALIZATION

The price of groundfish products rose rapidly during the year 1990. In August of 1990 the groundfish sections of the new Fund became active. An inpayment of 1% of f.o.b. of the export value was decided for that month for all groundfish. The prices in other sections of the Fund did not give rise to inpayments or outpayments at that time.

In spring 1991 the price of groundfish came to a new historic peak. In May that year the average price of frozen fish was 20% higher in real terms than in 1987 when the price was on a previous record level.

The proportional inpayments went up to 5% in April 1991. These high inpayments coincided with the main fishing season and consequently this high inpayment met a profound discontent among the subjects concerned. During the summer months of 1991 the high prices leveled out and began to fall again in August 1991. High inpayments were paid to the Fund during these months of very high prices. But at the same time signs of overheating of the economy became evident. Upward pressure was on prices, wages and interest rates. But in a rather short period of time, nearly 1.5 billion Icelandic Krönas (U.S.$ 260 million) were paid into the Fund and neutralised. This reduced the money supply to a certain extent and curbed inflationary expectations. The labour unions agreed to postpone wage increases which they were entitled to, according to previous labour market agreement. This was done to allow the fisheries sector to improve its international competitiveness and to build up reserves to use during periods of low prices. All this made the necessary preconditions for more stability in the Icelandic economy.

For the period from July 1990 to January 1992 when inpayments to the Fund were stopped, the total income of the groundfish sections of the Fund accrued to 2.5 billion Icelandic Krönas (U.S.$ 430 million) or equivalent to 5% of the total export income of groundfish products in 1991. In Fig.4. the effects of the price equalization system can be seen.

The general consensus among economists and representatives from the various interests groups in Iceland has been rather univocal. The price equalization system has been successful. It has been proven that such an additional policy-tool is very helpful, if not a necessary part of the stabilization policy.

## APPENDIX 1.

The law of the new Fund prescribes that in each month the average market price in SDR for the products of the different sections are to be calculated. Let MPt stand for this average price for a specific section. Then t stands for the month when the board of the Fund makes its decision which will be effective for the next month, i.e. month = (t + 1). This price is adjusted for inflation with an index which shows changes in the purchasing power of SDR against prices measured by the consumer price indices in the five biggest industrial countries. The respective weights used are the same as those used to calculate the exchange rate of SDR. Let CPIt stand for this price index in month t and let RPt stand for the inflation adjusted price. It follows, therefore:

$$RPt = MPt/CPIt \tag{1}$$

Mathematically the formula for the basic price is the arithmetic mean of inflation adjusted marked prices for the last 60 months. Let BPt stand for the basic price then:

$$BP = (RP + RP\text{-}1 + ....+ RP\text{-}59)/60 \tag{2}$$

The next step is to evaluate the marked price MPt which is retrieved from data supplied by the exporters.

Next, the percentage difference between the inflation adjusted marked price and the basic price is to be calculated. Let PD stand for this difference:

$$PD = 1 - PD/RP \tag{3}$$

It is stated in the law of the Fund that 50% of this difference shall be the proportion of inpayment or outpayment. Now one parameter must be decided upon. This parameter is the so called price gap that can be, according to the law of the Fund, anywhere between 3% and 5% . The larger the price gap is, the less sensitive are inpayments and outpayments to changes in prices.

If we let PGt stand for the price gap and let PEt + 1 stand for the percentage of the f.o.b. value of export during next month, which is to be paid as inpayments or outpayments, then these payments are decided by the following formula:

$$\begin{aligned} &0.5(PDt - PGt) \text{ if } PDt \text{ is } > PGt \Rightarrow \text{outpayment} \\ &PEt + 1 = 0 \text{ if } -PGt < PDt < PGt \Rightarrow \text{neutral} \\ &0.5(PDt + PGt) \text{ if } PDt < -PGt \Rightarrow \text{outpayment} \end{aligned} \tag{4}$$

If PEt + 1 > 0 the firms should pay into the Fund in the month (t+1), while PEt + 1 0 the Fund has to pay price supplements out of each individual company's account, as long as that company has a positive balance in its account.

## APPENDIX 2.

During the active period of the Fund the following decisions concerning inpayments to the sections of groundfish products (as a percentage of f.o.b. prices) have been:

| | | |
|---|---|---|
| Aug | 1990 | 1.0% |
| Sep. | " | 1.7% |
| Oct. | " | 2.5% |
| Nov. | " | 3.9% |
| Dec. | " | 3.9% |

ABSTRACT

*Because of the abundance of fisheries resources around its islands, Japan has been the world number 1 fishing nation, producing more than 10 million metric tons of fish per annum for the past several decades. It is, however, not too much to say that its particular structure of fish marketing system has made it possible to maintain the highest level of fish production in the world and make such a marked growth in Japanese fishery.*

*Unlike many other countries, the Japanese fish marketing system has several channels before fish reaches the consumer. It is, however, quite an effective system, capable of managing a variety of different species caught from different areas as well as certain species sometimes caught in great quantities. In the present paper, the role of the fisheries cooperative association in fish producing areas and the fish wholesale market in fish consuming areas is illustrated.*

*In recent years, fish imports have increased tremendously, and some fisheries products have greatly improved in quality. These fisheries products tend to follow different marketing channels. The paper also touches on these special cases.*

*Unlike the E.C., the Japanese government hardly gives any subsidies to fishermen to compensate for falling fish prices. Instead, the government provides the fishermen's organization with funds for the construction of a cold storage, where fish is stored until prices have recovered.*

## 1. INTRODUCTION

The total supply of fish and fishery products in Japan in recent years has been 14 to 16 million MT in round weight. Of this total supply, about 10 to 12 million MT are supplied by her domestic fishery, and the remaining 3 to 4 million MT are imported.

On the other hand, the total demand of fish and fishery products in round weight is about 12.5 to 13.5 million MT, of which 8.5 to 9.0 million MT are for food use and the remaining 4.0 to 4,5 million MT for non-food use such as fish meal and feed for fish culture.

Japanese fish marketing system has been developed to support such a great deal of supply and demand of fish and fishery products. In the present paper, the existing fish marketing structure which was basically developed as "fresh fish market" is at first illustrated. Then, its recent deviation which took place in relation to change in the form of fishery products transacted will be analyzed.

## 2. JAPANESE PREFERENCE TO FISH

Until Japan officially opened her window to Europe and the United State of America in 1868, eating the meat of animals with four legs was taboo. This was due to the fact that Japan is surrounded by sea, and fish has been plentifully available as the source of animal protein.

In buying and eating fish, Japanese are extremely cautious not only in the taste but also in freshness, appearance, color, etc. Japanese often eat raw fish, i.e., 'Sashimi', to enjoy the original taste of fish. While eating fish, Japanese also appreciate to see the whole fish with head and every fin. Therefore, freshness and appearance are key factors to determine the price of fish.

Existing fish marketing structure in Japan has been developed taking into account these conditions.

## 3. EXISTING FISH MARKETING STRUCTURE

### *3.1 Specific Features of Fish Marketing*

Existing fish marketing structure in Japan is composed of a fish wholesale market in fish producing area and another fish wholesale market in consuming area. How such two tier fish marketing structure was historically developed is not clearly known. However, it is almost sure that the fish wholesale market in consuming area was developed in much earlier stage, whereas those in fish producing area were mostly developed in around 1930 with the encouragement of the government.

It is important to note that existing fish marketing structure in Japan has been developed as a market mainly for "fresh fish". Incidentally this two tier fish market structure satisfies with the following two conditions :

i) Fresh fish are perishable and are quickly spoiled. There fore, fish has to be quickly transacted until it reaches to consumers.

ii) The price realized at the markets must be fair and reason able to both fish producers and consumers.

### *3.2 Existing Fish Marketing Structure*

As referred in 3.1 above, there are two different types of fish wholesale markets. These function as follows : (see Fig.1)

#### 3.2.1 Wholesale Market in Fish Producing Areas

At first a fisherman brings his catch to a fishing port and consigns the catch to a fish wholesaler. Then, with the arrangement of the wholesaler fishes are auctioned to the buyers. In this way, fishes go to the buyer, who offered to pay the highest price. Here, the buyers are fish dealers who intend to ship the fish to another wholesalers in consuming areas, local middlemen who intend to sell the fish to local retailers, fish processors or local fish retailers. (For further detail see Odaka's paper)

It may be very clear from the foregoing that fish bidden by local middleman, local retailer and fish processor are locally consumed. Thus, only fish bidden by fish dealers are shipped at his own risk to another fish wholesaler in fish consuming area.

By 1988, throughout the country there were 1077 fish wholesale markets in fish producing areas, the majority of which are run by unit FCAs. This means that the majority of marine FCAs act as fish wholesalers in fish producing area. However, some of them are prefectural federation of FCAs, fish marketing company or at extreme case individual.

### 3.2.2 Wholesale Market in Fish Consuming Areas

Fish market facilities in consuming areas are normally provided by local governments like the Tokyo Metropolitan Government, Osaka City Government, etc. In a same wholesale market there are, in principle, two fish market companies or more, which act as fish wholesalers in fish consuming areas.

Fish dealers in fish producing areas as referred in (3.2.1) above will ship his fish and consign it to a fish wholesale company in fish consuming area. Similar to fish producing areas, with the arrangement of the fish wholesaler the fishes are auctioned to the middlemen who belong to that fish market and are authorized to attend the auction. In recent years, however, owing to the standardization in the quality of fishery products, some of fishery products are directly sold to the middlemen at a mutually settled price.

Each middle man has own sale lot in the site of fish market, and sell fish bought from the fish wholesaler to fish buyers by negotiation. Here, the buyers are retailer, supermarket, restaurant, "Sushi shop keeper, etc., who come to the fish market every day to buy fishes from the middlemen.

## 4. DIFFERENCE BETWEEN FISH MARKET AND VEGETABLE MARKET

According to a law of wholesale market, both fish and vegetable are regarded as perishable food. However, as for vegetable there is no marketing structure in its producing area. A farmer brings his vegetables to his agricultural cooperative association (ACA). Then, after grading and packing them, the ACA ships the vegetables to a vegetable wholesale market in consuming area. Thus, unlike fish, there is no transaction of vegetable in producing area.

The following are said to be the reasons why a fish wholesale market has been developed even in its producing areas :

i) In comparison with vegetable, fish is treated as more variety of commodities in fish market, as the price of fish is determined not only by species but also by size. Furthermore, fish can be transacted as a commodity, only when it is strictly sorted out by species, size, freshness, appearance, color, etc. Such a sensible assortment of fish is not possible without a wholesale market in fish producing area.

ii) Fish is extremely perishable and requires very fast transaction and shipment to its consuming areas. The existence of a fish wholesale market in fish producing areas, especially that of fish dealer who takes charge of fish shipment, makes this prompt shipment possible.

iii) The price of fish is determined at a fish wholesale market in fish producing area, right after fishes were landed. This makes it possible for fishermen to recover his sale proceeds as quickly as possible, and this will facilitate the continuation of his fishing business.

iv) The fish wholesale market is available all along the coast of Japan. This makes it possible for fishermen to land his catch at the nearest port from his fishing ground and to save his navigation time and cost.

For the above reasons, the fish wholesale market in fish producing areas plays a vital role in the fish marketing.

## 5. SPECIFIC FEATURE OF FISH MARKETING IN RECENT YEARS

### *5.1 Development of Frozen and Other Processed Fish Products*

Since around 1970, the installment of quick freezer into distant water fishing boat, particularly tuna and squid boats, development of fish processing technics for high quality fishery products, enlargement of cold chain system up to consumer's homes and so forth have resulted in considerable change in the form of fishery products from "fresh fish which is perishable" to "frozen and other processed fish products" such as 'Surimi' based products.

In other words, in those days marketing of frozen and other processed fish products has become popular, although marketing in fresh fish still remains. Naturally, these new fishery commodities are of highly preserved and of highly standardized in quality. As these new fishery commodities are not perishable foods, they are not necessary to be auctioned.

With an increase in the volume of these new fishery commodities, auction, which is the basic pattern of fish transaction at fish wholesale market, has been gradually replaced by cross trade between a fish wholesaler and a middleman. (see Fig.2) As a result, a fish wholesale company in consuming area, which was originally a fish consignee, has become a fish trader who buys fish and sells it to others.

On the other hand, marketing of these processed fish commodities outside the existing fish marketing channels has increased. In this respect, it should be mentioned that there is no legal rule that fish and fishery products have to be sold through the existing fish marketing channels.

The following may be some typical diversification of fish marketing patterns, which took place in recent years.

i) Marked increase in the import of shrimp, tunas and salmons by powerful trade companies has created either their own marketing routs for these commodities or routing only through wholesale market in consuming area.

ii) Consumers buy fish more at supermarket than at fish retailer, resulting in a decrease in the number of the retailers. Eating out at a family restaurant, which is, in many instance, a chain store, has also become popular. As a result, these enterprises try to create their own fish marketing channels.

iii) Fish producers, individual fisherman, FCA or the federation of FCAs, also attempt to create their own marketing channels by establishing their fish shipment base close to fish consuming area, by skipping the wholesale market in the fish producing area.

iv) Direct sale of fish and fishery products by FCAs to consummers' cooperative associations, daily meal supply enterprises, a chain of fish retailers, etc. has been also practiced. Sometimes, fish producer or fish dealer in fish producing area sell live Kuruma prawn, prepared puffer 'Sashimi', etc. directly to consumers.

### *5.2 Consumer's Gourmet Preference and Live Fish*

In recent years, marketing live fish has become very popular throughout the country. The share of fresh fish auctioned against the whole fish transacted at Wholesale Fish Markets has followed a steady declining trend (see Fig.3).

Some live fishes are air-lifted to Japan from abroad. Air lift import of sea breams and spiny lobster from New Zealand has been now popular. In many instances, fish are airlifted under the status of winter sleep.

Although tuna can not be kept alive for shipment, in recent years fresh tunas are imported by air with crush ices at ice temperature. In this way, the quality of tuna meat can be best maintained, resulting in higher price.

## 6. PRICE MAINTENANCE OF FISH IN JAPAN

In around 1960 a great fluctuation of fish price in relation to the seasonal change in fish landings was recognized, and a need to expand the capacity of cold storages was keenly stressed. For the period from 1975 to 1990, the number of cold storages increased from 3761 to only 3903. During the same period, however, the capacity of the cold storages doubled from 14 million cubic meter to 26.6 million cubic meter (see Table 1).

Thus, in spite of the oversupply of quality fish due to its increased import, the price of fish seems to have been well stabilized. This is due to the fact that at the time of its oversupply the fish is stored at a cold storage until the price is recovered. Thus, it is well assumed that an ample space of cold storage capacity plays a role of stabilizing the price of fish.

During the past years the cold storage holding of fish has increased from year to year, and in recent years it has always remained at the order of 1.5 million MT, which is equivalent to nearly 20 % of the annual total supply of fish for food use (see Table 2).

During the 1970s the price of fish was generally stagnant. However, in terms of the consumer's price index number, over a period from 1975 to 1990 the price of fish has always followed a slightly higher upward trend than that of meats. (see Fig.4)

## 7. CONCLUSIONS

In recent years, from the viewpoint of Consumers fish and fishery products have been regarded as favorite food items or delicacies rather than the source of animal protein.

The demand of quality fish will last forever. From the viewpoint of fish retailer, supermarket, 'Sushi' shop keeper, etc. existing fish wholesale market needs to be retained as a place to assort a variety of different fish species.

# Fishery Cooperative Association in Japan and its Vital Role in Fish Marketing

**Natsuko Odaka[a] and Tadashi Yamamoto[b]**

[a]RA43, Kamihirama 1254, Nakahara-Ku, Kawasaki, Kanagawa Z11, Japan

[b]College of Economics, Nihon University, Tokyo Shinjuku 1-23-5-703, Shinjuku-ku, Tokyo 160, Japan

ABSTRACT

*Japan has an unique fishermen's organization in the world, as almost all fishermen in Japan are organized into a fishery cooperative association (FCA). There is a FCA at every fishing village. As a result, Japan has a complete network of FCAs throughout the country.*

*Japan's FCAs are involved in fish marketing activity, through which fishes caught by member fishermen are sold by means of auction.*

*Out of its all economic activities, FCA's fish marketing activity plays a key role for the economic stability of both FCA and its members.*

## 1. DEVELOPMENT OF FISHERMEN'S ORGANIZATION IN JAPAN

During feudal era of Japan which lasted until 1867, a fishing right was granted to a fishing community. Although there was a tie among fishermen in the community, during this period there was no fishermen's organization.

In 1901, the first fishery law was promulgated in Japan, stipulating that a fishing right was to be granted to a fishery association (FA). This implied that fishermen are not allowed to operate in fishery, unless they become the members of FA. In this way, throughout the country all fishermen were organized into FA. In those day, the FA was responsible only for the management of fishery based on the fishing right granted to them.

In 1910 the fishery law was revised, allowing FA to engage in economic activity for the benefit of fishermen. With this revision, some FAs began to operate in fishing marketing. By 1920 there were a total of 3,646 FAs, of which those engaged in fishing marketing were only 744 or 20 % of total.

In 1933 the fishery law was again revised. As a result, the FA was converted into the form of a fishermen's cooperative association (FCA) with a capital shared by members and started to involve, in addition to fish marketing, in saving and credit business to the members. At the same time, the government began to provide the FCAs with fisheries facilities such as fishing port, fish landing pier, fish marketing shelter, ice making factory, etc.. This was the occasion, when many Japanese FCAs began to involve in fish marketing by eliminating a direct fish transaction between fishermen and fish merchants.

## 2. FISHERY COOPERATIVE STRUCTURE IN JAPAN

Japan's fisheries cooperative structure is composed of three tiers,i.e., an unit FCA at a fishing village level, a prefectural federation of FCAs at a prefectural level and a national federation of FCAs at national level.

As of March, 1990, the total number of unit FCAs throughout the country accounts for 2,118. Some 535,000 fishermen belong to these FCAs either as full or associated member.Above unit FCAs there is a prefectural federation of FCAs at each prefecture, which accounts for 43 federations throughout the country. Above these 43 prefecture federations of FCAs there is a national federation of FCAs in Tokyo, which is known as Zengyoren.

## 3. FISH MARKETING CHANNEL IN JAPAN

Japan's fish marketing channel is basically composed of : (See Fig.1 of Miki's Paper)

i) Fish wholesale markets in fish producing areas, and

ii) Fish wholesale markets in fish consuming areas.

In most cases, FCA acts as fish wholesalers in fish producing areas, as FCAs are developed all along the sea coast and have their own fish landing facilities and market shelters. In contrast to fish producing areas, facilities for fish wholesale market at consuming areas are provided by local governments, and in most cases private fish marketing companies act as fish wholesalers.

Fishes are transacted by means of auction at both level of fish wholesale markets. However, this paper deals with mainly how FCA acts as fish wholesaler in fish producing areas.

## 4. ACTIVITIES OF THE FISHERY COOPERATIVE ASSOCIATION (FCA)

Fisheries Cooperatives is a non-profit making organization. It is an economic and social entity with its main purpose to improve their social and economic well being. It is organized by pooling their resources and efforts together to achieve a common goal. The FCAs are mainly multi-purpose and full service organizations which are engaged in a wide variety of services for the interest of its members. Generally, the fisheries cooperatives are engaged in economic and non-economic activities as listed below :

### *4.1 Economic Activity*

(i) Fish Marketing Business

This is one of the most important economic activities of the FCA. It assumes responsibility in selling the members' catch through auction or bidding. FCA's fish marketing helps to strengthen the financial status of the FCA, and at the same time assures the income of members by a fair price of their catch, which is realized through auction.

(ii) Credit Business

Saving accounts are opened for every members, and the proceeds from the auction, after deducting FCA commission, is saved at their own account. The surplus of such savings are used for fisheries loan to other members.

(iii) Supply Business

The FCA supplies, in many instances, the fishermen with fishing materials and also household daily necessities at reasonable prices. The payment is automatically deducted from the savings account of the fisherman.

(iv) Utilization Business

This is referred to the use of FCA owned facilities such as cold storage, warehouse, boat parking lots and other facilities. The fishermen pays a certain amount of fee for the use of such facilities.

### *4.2 Non-economic Activities*

#### 4.2.1 Fisheries Management based on Fishing Right

This includes (i) Establishment of closed season, closed sea area, restriction of fishing gears, minimum size of fish to be caught, catch limit, etc. for the conservation of fisheries resources, (ii) fair allocation of fishing grounds. (iii) Stocking fish seeds into sea to increase the productivity of natural fisheries resources, (iv) surveillance of fishing grounds, and so forth.

#### 4.2.2 Guidance and Education of Member Fishermen

This includes improvement of fishing/aquaculture technics, improvement of home management, encouragement of youth activities, and so forth.

## 5. FCA'S FISH MARKETING ACTIVITIES IN DETAIL

Fish is landed at one of over 2,000 fishing ports, and it is at this very point that Japan's fish marketing channels starts.

### *5.1 Japan's Fish Marketing in the past*

Japanese fishermen have had a long and bitter experience of being exploited by fish merchants or middlemen who dominated and controlled fish trade for many centuries. The marked development in establishment of FCA's fish marketing activity in around 1933 therefore liberated Japanese Fishermen from economic slavery to economic freedom.

### *5.2 FCA's Fish Marketing Practice*

The system operates in such a way that the member fishermen hand over/consign their catch to FCA for sale. At this point, it is important to note that the FCA does not buy the fish but act as consignee.

With fish consigned by fishermen, the FCA holds fish auction at its fish marketing shelter by inviting fish buyers once or twice a day depending on the timing of fish landing. On this occasion the FCA acts as auctioneer, and fishes go to the buyer who bid the highest price. Then, the FCA collects the payment from fish buyers on behalf of fishermen.

It is important to note that, although Japanese fish marketing system was transferred from "direct transaction between fishermen and fish merchants" to "FCA fish marketing system", these fish merchants were allowed to attend at FCA fish auction and were able to continue their business.

In return to this service, the FCA charge the member fishermen a commission which may vary from 3 to 5 %. Through this FCA fish marketing system, a fair price for their fish is assured. On the other hands, the revenue received as the commission assists to strengthen the financial position of the FCA. On the average, about 39 % of total revenue made by FCA is from this fish marketing business ( see Table 1 ).

At present, throughout the country there are more than 700 fish wholesale markets in fish producing area, of which more than 80 % are FCAs. FCAs deal with more than half of the total catch landed throughout the country.

### *5.3 Significance of FCA Fish Marketing System*

In general the importance of FCA marketing business can be summarized as follows ;

(i) It provides the FCA with a stable and steady income, as such fish marketing practice lasts forever.

(ii) The costs for fish marketing business are small, but the profits are high.

(iii) There are very little risks involved, since the buyers take all risks until fish reaches to another buyer.

(iv) Since the FCA takes charge of collecting the proceeds from the buyers, it has an opportunity to deduct its dues from the members income before depositing it on their accounts.

(v) It offers a good opportunity to fishermen to meet together every day during the time of auction and exchange ideas about their common problems and interests.

**TABLE 1.**
**TOTAL REVENUE REALIZED BY ALL UNIT FCAS.**

| Kind of business | Total | % |
|---|---|---|
| Total | 140,185 | 100.0 |
| a. Marketing business | 55,445 | 39.6 |
| b. Credit business | 24,625 | 17.6 |
| c. Supply business | 18,030 | 12.7 |
| d. Utilization business | 9,052 | 6.5 |
| e. Others | | |
| i. FCA own fishing business | 13,267 | 9.5 |
| ii. Processing business | 3,563 | 2.5 |
| iii. Insurance business | 2,077 | 1.5 |
| iv. Other Business | 14,124 | 10.0 |

# Supply and Demand of Fish and Fisheries Products in Japan

**Guylaine Bourguignon**

Fisheries Management and Economy Division, National Research Institute of Fisheries Science, 2-12-4 Fukuura, Kanazawa-Ku, 236 Yokohama, Japan

ENSA-Rennes, DEERN, 65, rue de Saint-Brieuc, 35042 Rennes, France

RÉSUMÉ

*Après la 2nde guerre mondiale, en reconstruisant son industrie de pêche, le Japon devint le plus grand producteur de produits halieutiques dès les années 60 - une position qu'il détient toujours bien que le tonnage de sa production en pêche baisse ; moins de 10 millions de tonnes en 1991. Le développement de la capacité de capture en pêche a permis au Japon d'avoir une spécialisation à l'exportation jusqu'en 1971, année durant laquelle les importations furent supérieures en valeur aux exportations. L'augmentation du pouvoir d'achat des japonais, grâce à la croissance économique, a entraîné une disponibilité d'achat pour les produits alimentaires, dont les produits halieutiques. Le déficit de la balance commerciale pour les produits de la mer n'a cessé de croître. De nos jours les exportations représentent à peine 5 % des échanges mondiaux en valeur, tandis que les importations sont à plus de 30 %. Plus qu'une préférence de l'alimentation à base de poisson, toute l'historique du développement de l'industrie halieutique japonaise témoigne de la stratégie d'un pays pauvre en ressource alimentaire se dotant de facteurs pour produire les protéines les plus accessibles. C'est ainsi, que les protéines de poisson entre pour 21,5 % dans l'alimentation au Japon, alors qu'au Etats Unis seulement 2,5 % y prennent part.*

## 1. INTRODUCTION

After the 2nd world war by rebuilding its production capability Japan became the world's largest fish producer in the later 1960's - a position it still holds, though its production is decreasing ; less than 10 million tons in 1991. The build-up of the Japanese fishing industry led to the country becoming the world's largest fish exporter in the 1960's. Early 70's Japan began to experience high economic growth which had a corresponding rise in the nation's standard for food products.

This brought an increase in the country's consumption of its own catch and a rise in imports of medium and high grade fisheries products. Imports exceeded exports in value for the first time in 1971. This trade deficit has quickly grown, exports have decreased to 5 % of the world fishery trade, whereas imports have increased to about 30 %.

Of course, one of the major reason for the size of Japanese fish market is the preference for fish in Japan. Fish protein is an important component of Japanese daily diet. For example, in the U.S. only about 2.5 % of protein is from fish whereas in Japan 21,5 % of protein consumed is from fish (Fig.1).

## 2. TRENDS IN JAPANESE FISHERY PRODUCTION

Japan's fishery production has continued to increase even after 1977 (Exclusive Economic Zone's establishement). Since 1972, production has exceeded 10 million tons annually. However, since 1989 it is on a decreasing trend, and has fallen at 9.8 million tons in 1991.

### *2.1 By fishery zones*

The establishment of 200-mile zones by most coastal nations and the reduction in fishery allocations to Japanese fishermen forced major change in distant-water fishery. Production within foreign 200-mile zones has decreased dramatically, mostly within U.S. and ex-USSR zones ; from 2.2 million tons in 1978 to 1.5 in 1990 ; and concerns principally high-seas fishery. However, production value has been declining since 1984, by the loss of allocations for higher valuable species within foreign 200-mile zones. Production in offshore fishery, which operate mainly in the waters off Japan 12 miles, accounts for more than half of total Japanese fisheries production, but its value has decreased since 1982, because of overproduction of non-valuable species like sardine. Coastal fishery production has been stable around 3.3 million tons since 1980, including marine aquaculture.

It is the most important component of Japanese fisheries considering is value due to higher valued target species. Marine aquaculture accounts for about 11 % of total production and 25 % of total value. Inland-water fishery, including aquaculture, is a minor component of the fishery sector (Fig.2).

### *2.2 By major species group*

Since 1960, the composition of the Japanese fisheries has changed, with the increase of non-valuable species. In 1990, 38,9 % of the production was made up by sardine, catched in offshore fishery. Sardine production depends on periodic natural fluctuations, and in a close future production might decrease (Fig. 3).

## 3. DOMESTIC FISHERY PRODUCTION BY FOOD USE AND NON-FOOD USE

The production's drop in distant-waters fishery, as well as the production's rise of lower valuable species in offshore fishery, have resulted in a break down in the domestic production of fisheries products for food. In a whole, Japan supplies is market at 79 %, when it was at more than 100 % in 1970. In 1975, 78 % of the production was dedicated to food use, in 1990, only 63 % (Fig. 4).

### *3.1 Use of fishery production for non-food*

Growth in fishery production for non-food correlates with the development of mariculture and the big increase in sardine production. Aquaculture sector requires reduction for fish culture. Export trade concerns mainly fish meal and oil.

### *3.2 Use of fishery production for food*

By catching less and less valuable species, the use for fresh consumption of Japanese production has declined, and conversely production of salted and smoked products has increased. Production of fish paste has decreased since the loss in 1988, of Cod's allocations in U.S. fishery zone. The canned industry concerns canned sardine, and has decreased after competition with countries like Thailand, Korea... in canned tuna and salmon (Fig. 5).

## 4. SUPPLY AND DEMAND OF FISHERIES PRODUCTS FOR FOOD

### *4.1 Trends in import and export*

In early 70s, with the rise in household income, flourishing Japanese fisheries industry's aim was to supply its domestic market. Anyhow, Japanese products were too expensive to be exported, futhermore economic growth has enable to meet the growing demand by importing.

Since 1985, import has increased by 30 %, export has decreased by 39 %, while demand goes up sligthly by 4,5 %, opposite to that, production has decreased by 15 %. Rise in import will steadily continue, instead demand is stagnant, with an insufficient production in quantity and valuable species. Export might decrease more, considering fluctuation in sardine production, which generate export of canned sardine and feedstuff products (Fig. 6).

### *4.2 Structural change in import*

(1) **Products group** (Fig.7) : Japan has always purchased fresh, chilled...fisheries products. But since its production can not meet the domestic demand, import of fresh, chilled... fisheries products has increased to account for 83 % of total import fisheries products in volume in 1990 (table 1). In 1985, import of fish paste became significant after the terminating of allocations in U.S. Cod's fishery zone.

(2) **Major species** (Fig. 8) : Five species, shrimp, salmon, tuna, squid and octopus are target in Japanese import. But, imports are more and more diversified, when sharing 49 % of import volume in 1975, this five items compose 38 % of import volume in 1990 (table 1).

## 5. TRENDS IN FISHERIES PRODUCTS CONSUMPTION

The demand for direct human consumption increase slightly A large variety of fisheries products are consumed by the Japanese people. The preference for fresh, chilled... products is still there, 37,5 % of consumption, but consumption of salted, smoked, dried products is increasing (more than 35 % in 1990, when it was at 29 % in 1985) (Fig. 9). General trend is that processed fish and shellfish products are popular in cities, whereas unprocessed products is preferred in rural areas. Salted, smoked and dried products is a part of Japanese traditional fish processing industry and eating habits, particularly with salted salmon. The largest amounts of fresh fisheries products purchased in order of volume were squid, shrimp, tuna, jack mackerel, saury, sardine, yellowtail and mackerel. Oyester, shortnecked clams and other shellfish are also consumed in larges volumes.

### *5.1 Yearly consumption by quantity*

Fisheries products were the first source of animal protein for the Japanese people. Since 1960s, fundamental changes have taken place in their dietary patterns. The average calorie intake per person has grown from 2200 calories a day in 1960 to around 2600 nowaday. When consumption of meat was increasing by 6.5 % annually, seafood consumption grew

at slower rate (1,5 % per year). In 1990, per capita consumption is about 72 kg on a round weight basis (Fig. 10). This accounts for 42 % of the total daily animal protein supply of 45.1 grams per person. Japan's exceptionally high per capita consumption of fisheries products differs significantly from that of other developed nations which depend upon livestock products for their protein supply.

### *5.2 Annual price rank between main food items*

In 1985, seafood products have become with beef the most expensive food items (Fig. 11). Within the meat sector the consumption of pork and chicken has risen faster than of beef, untill 1980. Instead of been the most expensive food item, consumption of beef still rises, because of low level of consumption. This is to correlate with the expansion in domestic consumption of that were once luxury and expensive fish like tuna, salmon, shrimp... The tendency of selective consumption result in a price inflation for target species like flatfish more expensive than beef (Table 2). In 1970, only tuna and yellowtail were ranging between beef and pork price.

In 1988, eight species were on this side, and most fish were more expensive than chicken, except for the fish caught in bulk such as codfish, saury and mackerel.

Consumer price index shows a higher growth in fish and shellfish price than for other food items (Fig. 12). Rising income has strengthened Japanese demand for higher quality and expensive marine products types as salmon, shrimp, tuna...

## 6. CONCLUSION

In the past twenty years, Japan has moved from been the world's largest exporter to the largest single importer of fisheries products. Marine products account for the largest single component of Japanese food imports. This revearsal in trading position can be attributed to various factors : decreased domestic production resulting from stock depletion and the introduction of EEZ, strengthened domestic demand for high valued mainly imported species, and declined competitiveness of Japanese fisheries products on export due to the appreciation of Yen.

Japan Fisheries Agency has pronosticated for year 2000, a production of 11,600,000 tons, a domestic demand of 16,050,000 tons. That means an annual growth less than 1 %. Has Japanese demand has reached contentment ?

# Dual Structure of Japanese Marine Fisheries and Role of Fisheries Statistics in Fisheries Administration

**Tadashi Yamamoto**

College of Economics, Nihon University, Shinjuku 1-23-5-703, Shinjuku-ku, Tokyo 160, Japan

ABSTRACT

*Statistics are basically utilised for the economic analysis of the national economy or a certain sector of the national economy. However, only fishery statistics are utilized for two different purposes as follows : (1) Statistics needed for the economic analyses of fishery and (2) Statistics needed for the biological analysis of fisheries resources.*

*This is due to the fact that fisheries resources are renewable and annual change in its abundance has to be assessed from year to year in connection with fisheries' management. When emphasis is given to fishery statistics for biological use, those needed for economic analysis are apt to be ignored.*

*Fishery statistics needed for the biological analysis are catch and fishing effort data broken down according to the fishing areas.*

*In the present paper, therefore, the author will try to clarify, based on his past experiences, the following points :*

*1) the type of statistics needed for economic analyses of fisheries ;*
*2) the type of basic analyses to be made based on fisheries data as specified in (1) above ; and*
*3) the most effective way of collecting fisheries data as defined in (1) above.*

## 1. INTRODUCTION

### *1.1 Place of Fisheries out of National Economy*

Before World War II, agriculture and fisheries were major sectors of Japanese national economy. In those days, fishery products like canned salmon and crab and dried abalone and kelp, etc. were the important export commodities subsequent to silk.

After World War II, owing to the marked progress of secondary and tertiary industries, however, Japanese fishery has been a small sector of the national economy, being only 0.35 % of her GDP by 1990.

Owing to an increased income of Japanese people, demand for quality fish and fishery products began to increase since around 1970. Thus, Japan has been now the world largest fish import country. By 1989, Japan's import of fish and fishery product amounted to US $ 10.1 billion, which was 28.1 % of the world total import of fishery commodities.

### *1.2 Place of Marine Fisheries out of the Whole Fisheries*

Japan is an island country. Although it has some inland water fisheries, its production is insignificant in quantity term. With the exception of fresh water culture for eel, smelt fish, carp and rainbow trout, commercial capture fisheries are seldom practiced in the rivers.

For the above mentioned reason, discussions hereunder will be limited to marine fisheries, unless otherwise stated.

## 2. DUAL STRUCTURE OF MARINE FISHERIES

### *2.1 The Meanings of Dual Structure in Marine Fishery*

From socio-economic viewpoint, marine fisheries in Japan is divided into two categories as follows :

(1) Household Fishery

This fishery is undertaken to maintain the livelihood of the fishing household and is operated, in most instances, by its family members. The size of fishing boat in use is powered boat of less than 10 gross tons, non-powered boat or without boat. The household fishery is more or less equivalent to "coastal fishery" in Japan.

(2) Capitalistic Fishery

This fishery is undertaken to pursue a profit, and is operated, in most instances, by hired fishermen. The size of fishing boat in use is inboard powered boat of 10 gross ton and above. In general, offshore and distant water fisheries in Japan are regarded as capitalistic fishery.

Marine fishery in Asian countries also forms "dual structure". In Asian countries the household fishery is called "small scale fishery", whereas the capitalistic fishery is called "industrial fishery".

An economic unit engaged in fishery is statistically called "fishing establishment". In Japan and even in many Asian countries, the majority of fishing establishments are fishing households, which engage in the household fishery (see Table 1).

Even in EC countries such fishing household are likely to have existed. However, the fact has been hardly recognized due to the absence of statistical data on fishing households, which are normally obtained through a fishery census. It is important to note that the fishing households are also the objects of fisheries administration.

### *2.2 Dual Structure of Fishery and Role of the Government*

To clarify the dual structure of marine fishery is quite important for the government in the following respects :

(1) In general the income of fishing households is low, and hence their living condition is miserable. Needless to say, the role of the government is to improve the income and living level of fishing households.

For doing so, a variety of measures may have to be taken by the government. One of them may be to reduce the number of fishermen, although a question may remain how to reduce.

(2) In general the business of the capitalistic fishery is not always stable due mainly to price fluctuation of fish caught. In many instances, fisheries are seasonal. During a peak season of a particular fish the price goes down, whereas during the off season the price goes up.

One of the ways to prevent from the fall of fish price would be to store the surplus of fish at the cold storage until the price is recovered to a normal level.

## 3. NATIONAL FISHERIES STATISTICAL SYSTEM IN JAPAN

National fishery statistical system in Japan has been developed after World War II.

### *3.1 Statistical Items to Be Covered*

Fishery statistics are primarily utilized (i) for the evaluation on the progress achieved by the current fisheries development program and also (ii) for the planning of future fisheries development programs, although catch and effort data are required for stock assessment. So far, much emphases have been given to the collection of catch/effort statistics, leaving behind fishery statistics needed for the fisheries administration.

To meet the above two objectives, national fishery statistical system should cover at least statistical items as listed in Fig. 1a. These statistical items have been selected in accordance with "a principle of economic circulation".

(1) Number of fishing establishments by size and nature

Fishing establishment is an economic unit, which has an intention of doing fishing business. It is important to note that fishing establishments are the right object of fishery administration. The government should be aware of the number of such economic units by size and economic nature and their annual changes. These statistics are seldom available in developed countries.

(1') Number of fishing employee's households

The fishing employee's household is a household, that provides fishing laborer to other fishing establishment(s). Although it does not involve in fisheries production, it is also part of the objects of fisheries administration in terms of welfare of fishermen.

(2) Number of fishing boats

This statistics represent the size/capacity of fisheries production means. In many countries these statistics are available from the registration record of fishing boats, but they are not always very reliable.

(3) Number of fishermen

This statistics are indispensable as denominator to measure crude productivity of fishermen. The reduction in the number of fishermen is, in many countries, essential so as to increase the income of small scale fishermen, which ultimately improve their income and living condition.

(4) Number of fishing units

A fishing unit is composed of fishing boat, fishing gear and fishermen, and it is a technical unit to operate in fishing. Number of fishing units is counted by type of fishing gear employed. This statistics are useful for the planning of a fishery development program, and can be used as the substitute of fishing effort data in a country, where catch and fishing effort survey is not yet implemented.

(5) Statistics for the above (2), (3) and (4) are input data in the fishery, whereas catch statistics in quantity and value are output data. The latter statistics are quite important to assess the extent in the development of a fishery.

*3.2 Type of Fishery Statistical Surveys Required*

(1) Primary Phase of Fishery(see (1), (2) and (3) of Fig.1b)

To clarify the economic structure of a fishery, a fishery census is required at the interval of 5 or 10 years. To see the growth of a fishery, fishery production survey is required as a current survey. Fishery economy surveys are required for fishing households and fishing enterprises with objectives as given in Fig. 1b.

(2) Secondary and Tertiary Phases of Fishery (see (4) and (5) of Fig. 1b)

The fall of fish price greatly affects the operation of fishing business. To secure data needed to protect the fish producer from the fall of fish prices, fish marketing survey and fish cold storage survey are being undertaken Japan on monthly basis. However, the volume of fish and fishery products stored at cold storages at the end of every month has been indispensable information to international fish traders as well as fish producers abroad.

## 4. JAPANESE FISHERIES : CURRENT STATUS AND ISSUES

Japanese fishery statistics are being collected along the lines as illustrated in the above chapter. Based on these fisheries statistics the following can be clarified :

(1) Number of Fishing Establishments (see Table 1)

The total number of fishing establishments declined from 227 thousand in 1975 to 185 thousand in 1990 at an annual decreasing rate of 1.4 %. During the same period the number of fishing households decreased faster than that of fishing enterprises.

Japanese marine fisheries has a typical dual structure in terms of the number of fishing establishments, 95 % being fishing households and the remaining 5 % fishing enterprises.

(2) Number of Fishing Boats by Sizes (see Fig. 2)

The number of fishing boats declined from 327 thousand in 1975 to 277 thousand in 1990 at an annual decreasing rate of 1.1 %. During the same period the number of both inboard powered boats of any size and non-powered boats considerably decreased, whereas that of outboard powered boats slightly increased.

(3) Number of Fishermen (see Fig. 3)

For about ten years after World War II agriculture and fishery were the sanctuaries, which absorbed many unemployment and underemployment people. With the marked economic growth of the secondary and tertiary industries in the 1960s, quite many people in rural area moved into urban areas, resulting in sharp decline in the number of both farmers and fishermen.

Thus, the number of fishermen decreased from 780 thousand in 1954 to 370 thousand in 1990 at annual decreasing rate of 2 %.

(4) Fisheries Production (see Fig. 4a and 4b)

During the past about 30 years, Japanese fisheries production tremendously increased from 4.9 million MT in 1956 to 12.2 million MT in 1988 at annual in creasing rate of 2.9 %. The advent of new EEZ regime in 1977 greatly affected her distant water fishery, reducing its production from 4 million MT in 1973 to only 1.5 million MT in 1990. However, a marked increase in the catch of sardine due to the recovery of its resources made it possible to increase its total fisheries production at least until 1988 (see Fig. 4a).

Since 1988, however, the total fishery production has began to decline due to the decrease in the catch of sardine and Alaska pollack. (see Fig. 4b) Nevertheless, the total fishery production in value terms has not followed significant declining trend, as the fishery production from coastal fishery including coastal aquaculture in value

terms has followed a slightly increasing trend since 1988. (see Fig. 4c) This implies that fishermen's labour's productivity, i.e., average catch per fisherman per year in value terms have not declined even after 1988, as the number of fishermen still follow a clear declining trend.

(5) Species Composition of Marine Capture Fishery and Coastal Aquaculture

In recent years, Japan's marine capture fishery maintains high fishery production level, being around 10 million MT. Nevertheless, nearly 40 % of the total marine catch is occupied by sardine. The catch of fishes popularly consumed at home such as mackerel, squids, salmons, tunas, etc. are at the order of around 300 to 500 thousand MT per year. (see Fig. 5a) In order to fulfill the short supply of quality fish from marine capture fishery, coastal aquaculture has been developed for scallop, yellowtail, red sea bream, horse mackerel, coho salmon, etc. (see Fig. 5b)

(6) Economy of Fishing Households and Fishing Enterprises

(i) Fishing Household (see Table 2)

A fishing household has generally several income sources including the income from its own fishing. Average income of fishing household in recent years is around 6 million Yen, which is comparable with those of farm household in rural area and salary man's household in urban area. With this income level, the fishing household is able to find about one million Yen as surplus, which goes for his saving.

(ii) Fishing Enterprise (see Table 3)

Unlike fishing household, a fishing enterprise is seldom involved in side business. For this fishing enterprise, therefore, a cost and earning survey has been applied to see the size of profit realized from its own fishery business. During the past 15 years, the total fishing operational cost has been always close to the total earning due mainly to high labor and fuel costs. Therefore, in those days the size of profit achieved by fishing enterprise has been always marginal.

*1 : Fishing household engaged in coastal fishery using non-powered boat and po wered boat of less than 10 gross tons.

*2 : The income of a fishing household is generated not only from own fishery but also from salary/wage earned by some of its family members. Other incomes such as pension, interest, dividend, gift, etc. are also regarded as the income of a fishing household. These icomes are classified into as follows :

A = Total sale from own fishery — Total expense spent for own fishery.
B = The sum of salaries and wages which were earned by all members of the fishing household.
C = Any income other than the above A and B such as pension, interests, gifts, etc.

# Resource Valuation and Conflict
# by
# A. T. Charles and J. Catanzano

Deux des caractéristiques majeures du monde de la pêche sont (a) un état de surexploitation des ressources (utilisation excessive pouvant conduire à une destruction des ressources), et (b) l'existence de conflits pour l'usage des ressources halieutiques. Ces deux problèmes résultent de processus complexes, mais l'une des causes qui leur est certainement commune tient à l'inadéquation des politiques de gestion basées sur des « signaux » économiques dérivés des méthodes actuelles de détermination de la valeur des ressources. Un nombre croissant d'auteurs expriment des réserves sur l'aptitude de ces méthodes à déterminer la valeur intrinséque d'une ressource pour une société considérée dans ses différents usages potentiels, du fait du haut niveau d'incertitude et de l'état encore embryonnaire des méthodes utilisées.

Construits à partir de l'évocation de cas conflictuels, les textes rassemblés ici montrent tout l'intérêt de nouvelles approches des usages concurrentiels qui se côtoient pour l'accès aux ressources. Une évaluation des papiers contenus dans cette session offre l'opportunité de comparer les cas issus de pêcheries africaines, japonaises, des régions nord-américaines, d'espaces européens. Une telle comparaison nous permet d'entrevoir :

- des similitudes s'agissant des problèmes générés par les usages de nature multiple de la ressource;
- des zones d'ombre restant à aborder et pour lesquelles les fondements théoriques sont à repenser. On y perçoit les interrogations encore en suspens sur le rôle des institutions (dont les marchés), ainsi que celles sur le comportement des acteurs et les fondements de leurs choix et celles enfin relatives à la détermination de la valeur économique totale (valeur d'usage et valeur intrinsèque) des ressources halieutiques considérées comme un tout et notamment sans distinction d'usage.

Pour illustrer ces développements on trouvera ici l'évocation de conflits entre pêche récréative, pêche commer-

Two predominate characteristics of the world's fisheries are (a) resource over-exploitation (excessive stock depletion) and (b) the existence of conflicts in the use of resources. These two problems arise through complex processes, but surely one common cause is the inadequacy of management policies based on economic "signals" derived from present methods of resource valuation. An increasing number of authors are expressing reservations about the validity of these methods for determining the intrinsinc value of a resource to society in its possible alternative uses, given the high level of uncertainty and the embryonic nature of the methods involved.

With respect to conflict in fisheries, the papers assembled here demonstrate the interesting new approaches to the problem of handling competition among marine resource uses. An assessment of the papers compiled herein provides the opportunity to compare across a number of conflict situations in African, Japanese, North-American and European fisheries. Such a comparison indicates :

- similarities in problems due to the multi-use nature of the resources;
- a number of research areas in which theoretical foundations must be further elaborated. These "pending" questions deal with the role of institutions (particularly the formation of markets), the behaviour of individuals and the foundations of their choices, and determination of a total economic value (including use value and intrinsic value) aggregated across all uses.

To illustrate these points, this compilation includes a variety of conflict situations existing among recreational, commercial and subsistence fisheries or between domestic and foreign fisheries. The three papers of Potten *et al.*, Kusakawa, and Johnston and Emami all deal with what is perhaps the major area of conflict, at least in developed nations, that arising between commercial and recreational fishing.

ciale et pêche de subsistance ou encore entre pêcheries nationales et pêcheries étrangères. Potten *et al.*, Kusakawa ainsi que Johnston et Emami s'intéressent au cas de conflit peut-être le plus répandu, au moins dans les pays développés, qui met en jeu les concurrences entre pêche récréative et pêche professionnelle.

Le lien entre de tels conflits et la détermination de la valeur de ces ressources est clair ; les efforts pour la résolution de ces conflits et en fait les débats sur ce thème, doivent prendre en compte la compréhension des paramètres socio-économiques en jeu, en intégrant leur évolution selon les différents usages potentiels mis en concurrence. Potten *et al.* évoquent à ce propos la question relative aux coûts de la gestion et à leur prise en charge. Qui paye et qui doit payer ? Comment se répartissent les coûts de la gestion ?

On perçoit clairement à travers ces quelques cas les limites de la connaissance de ces ressources. Ces connaissances se développent le plus souvent encore à partir d'une prise en compte prioritaire voire exclusive des usages commerciaux. De fait, même lorsque les pêches non commerciales en viennent à dominer les pêches commerciales par l'effet qu'elles ont sur la ressource, il semble que les gestionnaires et les chercheurs restent attentifs quasi exclusivement aux pêches commerciales.

Les interactions et conflits entre pêches commerciales et pêches non commerciales – plutôt entre pêches récréatives et pêches commerciales comme il est fait référence dans le papier cité précédemment, ou entre pêche de subsistence et pêche commerciale (comme dans Geier *et al.* à propos des pêches de l'Alaska) – , ajoutent seulement quelques controverses sur la question de l'évaluation des flux économiques générés dans ces pêcheries. Ceci ressort également dans le travail de Queirolo et Johnston à partir des conflits potentiels entre pêches nationales et pêches étrangères impliquées dans des accords de coopération. Globalement, cela semble être l'une des deux plus importantes voies de travail identifiées par les auteurs sur ce sujet.

L'autre point fondamental abordé tient à l'incapacité des mécanismes de marché à permettre la détermination correcte de la valeur des ressources, puisque en plusieurs cas, notamment pour les pêches récréatives, et pêche de subsistence des populations indigènes d'origine maritime, les échanges se font sans référence au marché. En particulier la valeur de la ressource doit intégrer pas seulement les mesures monétaires de la valeur immédiate d'usage, mais aussi, (a) un ensemble complexe de facteurs socioéconomiques et culturels, et (b) les aspects dynamiques, considérant la ressource comme une forme de capital. On retrouve là par rapport à ce point particu-

The link between such conflicts and the matter of resource valuation is clear ; efforts at conflict resolution, and indeed any intelligent debate on the topic, must be based on some understanding of the socioeconomic values involved, and how these vary across the different uses. Potten *et al.* mention in this respect the question of management costs and their reimbursement. Who should pay and who actually does pay ? How are the management costs allocated ?

These papers note the limits of current knowledge concerning fishery resources, and the frequent focus on commercial uses in place of a balanced approach across all use categories. Indeed, even when non-commercial fisheries come to dominate resource use and resource impacts, it seems that management and research attention can sometimes remain focused on the commercial sector.

Interaction and conflict between commercial and non-commercial fishing – whether between commercial and recreational sectors, noted in the papers above, or between subsistence and commercial fisheries (as in Geier *et al.* for the case of Alaska) – only adds to controversies over how economic flows in the fishery sector are evaluated. This is reflected as well in the examination by Queirolo and Johnston of potential conflict between domestic and foreign fishing involved in "cooperative" arrangements. Overall, it appears to be one of the two most important fields for further exploration identified by the authors in this collection.

A second fundamental point is the inability of market-based mechanisms to properly evaluate fishery resources, since so many uses, notably recreational and subsistence/indigenous/Native fisheries, lie outside the normal market system. In particular, fishery resource valuation must incorporate not just monetized measures of immediate use value, but also (a) a complex package of socioeconomic and cultural factors, and (b) a dynamic aspect, namely the resource as a form of capital. We might suggest that underlying this point are a number of more general concerns, related to (i) the measure of utility and of non-use values for environmental goods (cf. the work of R.K. Turner), and (ii) the choice between immediate and long-term benefits, and the related matter of inter-generational natural capital flows.

In this context, some subjects are still subject to debate. While past research on recreational fisheries often measured "value" simply as a sum of expenditures by the fishers, Potten *et al.* note that the correct item to measure is the net economic value, including elements of both consumer and producer surplus. In this regard, it has been popular to use travel cost and contingent valuation methods which attempt to calculate what the market valuation "would be" if markets for recreational fishing in fact existed.

lier, un nombre de points plus généraux, reliés (i) à la mesure de l'utilité et la mesure de la valeur de non-usage pour les biens environnementaux (cf les travaux de R. K. Turner), ainsi que (ii) la question du choix entre les bénéfices immédiats et les bénéfices de long terme, et les liens intergénérationnels relatif aux flux de capital naturel.

A ce propos, quelques thèmes se voient remis en débat. Alors que les travaux anciens sur les pêcheries récréatives mesuraient souvent la valeur simplement comme la somme des dépenses engagées par les pêcheurs, Potten *et al.* font remarquer que la façon correcte de mesurer cette valeur revient à mesurer la valeur économique nette incluant à la fois des éléments du surplus du consommateur et du producteur.

Par rapport à cela, se sont développées des applications de la méthode des coûts de transport ainsi que des méthodes d'évaluation contingente qui consiste en fait à simuler ce que serait la valeur s'il existait un marché pour les pêches récréatives.

L'utilisation de telles méthodes, qui peuvent aussi bien s'appliquer aux activités de subsistence (par exemple le cas des pêcheurs de l'Alaska), reste fortement discutable. Des incertitudes dans les méthodes utilisées pour les biens relatifs aux pêcheries non commerciales doivent raisonnablement nous conduire à reconsidérer les régulations économiques mises en place sur la base de la simple théorie néo-classique. En outre, de telles méthodes ne devraient pas manquer d'intégrer les éléments clés du comportement du pêcheur non professionnel. Larson et Johnston notent à ce propos que le comportement décrit par l'effet Giffen « une augmentation de la quantité demandée d'un bien en réponse à l'augmentation de sa valeur monétaire », pourrait bien se produire.

En recherchant des méthodes plus complètes, plus propices à l'intégration des différents facteurs du comportement que celles en liaison avec les signaux économiques classiques, l'attention s'est portée sur un nombre d'alternatives possibles. Cependant, celles-ci ont été tracées plus en référence aux analyses spécifiques à l'environnement qu'aux ressources marines, et leur applicabilité aux pêcheries devrait inévitablement augmenter, en partie du fait des besoins pour de nouvelles approches aptes à résoudre les problèmes de disponibilité limitée des informations et de complexité des mécanismes institutionnels.

Trois approches sont privilégiées dans cette session :

(i) L'approche comptable des ressources naturelles (Webster) qui vise à l'évaluation du capital naturel total considérant les ressources halieutiques comme une forme d'actif aux variations duquel

The use of such methods, which in theory can also be applied to subsistence activities (for example Alaska fishermen), remains highly debatable. Uncertainties in the very procedure to be used in valuing non-market fishery "goods" may reasonably lead one to re-evaluate economic regulations designed on the basis of simple neo-classical theory. Furthermore, such methods may miss key elements of recreational fishing behaviour ; Larson and Johnston note that Giffen behaviour, "an increase in quantity of a good demanded in response to an increase in its money price", could well occur.

In searching for methodologies more complete and more inclusive than that reliant on standard economic signals, a number of alternatives are gaining attention. While these are drawn more from environmental analysis than from marine resource studies, their applicability in fisheries will inevitably increase, in part due to the need for new approaches to deal with limited availability of information and complexity of the institutional mechanisms. Three approaches discussed in the papers of this section are as follows :

(i) Natural resource accounting approaches (Webster) take a perspective of evaluating the total natural capital in the fishery as a form of asset, and measuring changes in this asset. Such approaches are becoming increasingly popular in evaluations of "sustainable development" policy options.

(ii) Multi-criteria regional impact models, which Geier *et al.* are in the process of developing for the Alaska context, attempt to determine total socioeconomic impacts of policy changes. This concept has also been used elsewhere, as in the so-called Five Account Model that formed the basis for evaluating salmonid enhancement in British Columbia.

(iii) Perspectives based on "New Institutional Economics", emphasize the fundamental importance of institutions, and move beyond the simplistic assumption of pure and perfect competition. The NIE viewpoint is highlighted in two papers herein (Failler and Wilson ; Wilson and Lent), and alluded to in Queirolo's reflections on the asymmetry of information and its role in determining the efficiency of rational choices. This perspective represents not so much an alternative methodology as an alternative view of standard fishery concepts (such as rent-seeking), emphasizing the multidimensional nature of "value" and the importance of understanding the dynamics of fishery institutions and of human behaviour.

In conclusion, it must be pointed out that, in the fishery sector and in the environmental arena, a combination of

on s'intéressera. De telles approches sont devenues extrêmement utilisées dans l'évaluation des options de politiques de « développement durable ».

(ii) Les modèles multicritères d'impact régional, que Geier *et al.* tentent de développer à partir du cas des pêcheries en Alaska en essayant de déterminer l'impact socio-économique global de nouvelles politiques. Ce concept a été également utilisé ailleurs et notamment dans le cadre du FAM (Five Account Model), qui donnait les bases d'évaluation du réensemencement de salmonidés en Colombie Britannique.

(iii) Des perpectives basées sur la Nouvelle Economie Institutionnelle, mettent l'accent sur l'importance fondamentale des institutions et tentent de dépasser l'hypothèse simpliste de concurrence pure et parfaite. Le point de vue de la NEI est éclairée ici dans deux communications (Failler et Wilson ainsi que Wilson et Lent), alors que Queirolo fera quant à lui allusion au problème d'assymétrie d'information et au rôle qu'elle joue dans l'efficience des choix rationnels. Ces perspectives ne représentent pas véritablement une alternative méthodologique mais plutôt une alternative de vue des concepts classiques de l'économie des pêches (tel que « rent seeking »), soulignant l'aspect multi-dimensionnel de la mesure de la valeur et l'importance de la compréhension des dynamiques propres aux institutions de la pêche et au comportement des pêcheurs.

En conclusion on peut souligner, tout d'abord, que comme pour la plupart des biens environnementaux, ce sont les défaillances combinées de l'information, du marché et des interventions qui soulèvent la plupart des obstacles au principe d'un développement durable (ici une pêche durable). D'un point de vue plus positif, par conséquent, les papiers qui vont suivre représentent un effort significatif visant à :

(i) construire une approche plus large et plus explicite de la détermination de la valeur des ressources, et de l'évaluation des conflits en prenant en compte aussi bien les facteurs externes que les hauts niveaux de variabilité et d'incertitude ;

(ii) réviser et réévaluer les paradigmes classiques de la théorie des pêches et développer les nouveaux paradigmes et nouvelles méthodologies nécessaires.

En effet, en soulignant les objectifs multiples et les usages divers liés à ces ressources nous sommes amenés à prendre du recul par rapport aux modèles classiques pour aller vers des approches plus nébuleuses, plus multidisciplinaires qui représentent un véritable challenge pour la recherche sur les pêches.

poor information, market failures and inadequate management interventions present serious obstacles to the principle of a sustainable development (sustainable fishing activity in this case). On the positive side, however, the papers herein represent a significant effort to:

(i) build a broader and more comprehensive approach to the valuation of resources and the assessment of conflicts taking into account external factors as well as high levels of variability and of uncertainty.

(ii) review and reassess classical paradigms in the fishery theory and develop new paradigms and new methodologies as needed.

By recognizing the multi-objective and multi-use nature of the fishery, we are taken beyond traditional fishery models, into more nebulous, more multi-disciplinary approaches, that present real challenges to fisheries research.

# On Inferior Goods and Giffen Effects in Recreation Demand Analysis

**Douglas M. Larson[a] and Richard S. Johnston[b]**

[a]Department of Agricultural Economics, University of California, Davis, California 95616-8512, USA

[b]Department of Agricultural and Resource Economics, Oregon State University, Ballard Extension Hall 213, Corvallis, Oregon 97331-3601, USA

ABSTRACT

*Time-intensive goods like outdoor recreation are likely candidates for Giffen behavior when money price changes. For choices with binding money and time constraints, observable conditions for a good to be Giffen are developed. Model specifications and omitted variable biases are likely reasons why no Giffen recreation goods have been found.*

## 1. INTRODUCTION

The Giffen "paradox" has long intrigued students of economic theory. Put as a query, the phenomenon of interest is : "All else constant, under what circumstances will it be true that the quantity of a good demanded will move in the same direction as its price, thereby violating the first law of demand ?" The conventional explanation for Giffen behavior, in the neoclassical theory of consumer choice subject to a constraint on money income, relies on unusually-shaped preference. The strong inferiority of a good outweighs the negative substitution effect, so that the real income increase produced by a fall in its price results in a decline in its consumption. This story for the possible "existence" of Giffen behavior at the individual level has generally been dismissed as remote (George J. Stigler ; John R. Hicks) or "pathological" (Eugene Silberberg and Donald A. Walker) ; furthermore, William R. Dougan has argued that one cannot expect to find the behavior at the market level, as it is ruled out by the Walrasian stability conditions.

Recently interest in the phenomenon of Giffen behavior at the individual level has been renewed by both empirical evidence and theoretical developments. Raymond C. Battalio et al. reported the first experimental confirmation of Giffen behavior, in studies of the behavior of "poor" rat consumers. Otis W. Gilley and Gordon V. Karels (GK hereafter) developed a theoretical framework that provides an explanation for Giffen behavior consistent with the experimental

evidence. They showed that the presence of a second (minimum) constraint on consumption required for sustenance leads to Giffen behavior when both constraints are binding, because the consumer's response to a price increase consists only of an income effect. Both of these papers sound the same theme of the earlier literature, though : Giffen behavior is a relatively rare phenomenon, confined to poor consumers who have limited choice among staple items.

This paper's purpose is to suggest that Giffen behavior may be much more common than either the recent papers or earlier literature suggest, if only we know where and how to look for it. To develop this argument, we consider consumption of a commodity more common to consumers in rich, well-developed countries rather than in poor, less-developed ones : outdoor recreation.

A focus on outdoor recreation is useful for several reasons. First, outdoor recreation usually involves travel to a site distant from home, and consumption of the good itself involves spending time at the distant site ; thus, the time-intensiveness is a characteristic often associated with outdoor recreation. This illustrates well the case of consumption subject to two binding upper constraints, on time and money, rather than one upper (money) and one lower (nutrition) constraint as GK used. The idea that time constrains choice is well-developed in economics (e.g., Gary Becker ; Anthony DeSerpa). Both casual observation and empirical research point to the fact that in today's society many people wish they had more free time and more total time ; an example is a recent study which found "...almost half of American workers say that they would give up a day's pay to get an extra day off" (John P. Robinson).

A second reason for the focus on outdoor recreation is that its time-intensiveness makes recreation a commodity especially likely to exhibit Giffen behavior. Third, finding evidence that outdoor recreation may be Giffen puts the lie to the contention that Giffen behavior is most likely among poor consumers. Finally, because it is a nonmarket good, the Dougan argument concerning impossibility of the behavior in the aggregate is moot since recreation is not traded in markets within which Walrasian stability conditions must hold. Thus, we argue that not only is Giffen behavior potentially much more widespread than currently believed, but also that there is nothing to prevent it from being observed in the aggregate when the good in question is not marketed.

Having demonstrated the plausibility, indeed perhaps even the likelihood, of recreation giving rise to Giffen behavior, we turn to the empirical question of why such behavior has not been reported at all in the literature. While part of the reason is undoubtedly the strong self-selection against publishing such "unusual" results, we provide an econometric explanation for this absence of results confirming Giffen behavior for recreation. Despite long recognition of the importance of time in recreation choices, most empirical models in the literature are one-constraint models, explaining recreation trips as a function of money prices and budget, either because the time parameters are omitted or because a priori reasoning is used to collapse the two constraint problem into a single constraint problem. In either case, the likely effect is to mask possible Giffen behavior or to render the model incapable of testing for it. Thus existing empirical evidence in the recreation demand literature is largely unable to address the question of whether recreation is a Giffen good.

## 2. THE CHOICE MODEL

Consider an individual who allocates scarce time and money income in choosing consumption of three goods x, y, and z in order to maximize the utility function u(x, y, z). Each of the goods i, i=x, y, z, has a money ($p_i$) and a time ($t_i$) price of consumption, both of which are parametric to the individual, and the total amount of money income and time available are M and T, respectively. Given the focus of this paper, it is useful to think of x (and sometimes y) as a recreation good, such as trips of a fixed duration to a recreation site. It is necessary to incur both money and time costs of gaining access to recreation areas outside the home, and for recreation goods the time price is likely higher relative to the money price than for most other goods. For many non-recreation goods, the time price of consumption is low in relation to the money price, though some time must be spent in all consumption. Both constraints are assumed to bind throughout the analysis.

The constraints for the general model are written

$$M = p_x x + p_y y + z \qquad \text{(money)} \tag{1}$$

$$T = t_x x + t_y y + t_z z \qquad \text{(time)} \tag{2}$$

where the constraints are taken to be independent in order to have a two-constraint model, and both have been normalized over the money price of z, $p_z$. The choice problem is

$$\max_{x,y,z} U(x,y,z) \qquad \text{s.t. (1), (2)} \tag{3}$$

which yields (Marshallian) demands of the form $x^* = x(\alpha)$, $y^* = y(\alpha)$, $z^* = z(\alpha)$, where for notational convenience is the vector of all parameters of the problem : $\alpha = (p_x, p_y, t_x, t_y, t_z, M, T)$.

Consider an equivalent, indirect representation of the problem which first optimizes out the consumption of good z and then considers the remaining choice of x and y given the (prior) choice of optimal z. This version of the problem is useful because, by properly accounting for how the optimal choice of z conditions the feasible choice set for x and y, the optimal choices of x and y are apparent immediately in x-y space from the intersection of the two conditional constraints. This simplifies the visual understanding of relationships between goods in the two-constraint model and how they interact to give rise to inferior and Giffen good effects, without direct reference to the preference map.

Substituting $z^*(\alpha)$ obtained from (3) above into the preference function, and noting that the time and money available for choice of x and y are reduced because of the choice of $z^*$, the choice problem can also be written as

$$\max_{x,y} U(x,y,z(\alpha)) \quad \text{subject to the conditional budgets} \tag{4}$$

$$M_{xy} \equiv M - z^* = p_x x + p_y y \tag{5}$$

$$T_{xy} \equiv T - t_z z^* = t_x x + t_y y \tag{6}$$

Since the constraints are independent, a single x-y combination solves the conditional problem (4) since there are two unknowns and two equalities to be satisfied. The solution to this problem yields conditional demands of the form

$$x = \hat{x}(p_x, p_y, t_x, t_y, M_{xy}, T_{xy}) \tag{7}$$

$$y = \hat{y}(p_x, p_y, t_x, t_y, M_{xy}, T_{xy}) \tag{8}$$

which are identical to the unconditional demands that solve (3). That is, the same first order conditions hold for the conditional choice functions $\hat{x}(\cdot)$ and $\hat{y}(\cdot)$ in (7) and (8) and for the unconditional $x(\alpha)$ and $y(\alpha)$ that solve (3). In particular, no separability assumptions about preferences are required to obtain (7) and (8), unless z is treated as a composite commodity[1]. However, by solving the conditional budget constraints for $\hat{x}(\cdot)$ and $\hat{y}(\cdot)$, a convenient visual depiction of comparative statics results.

Figure 1 gives the visual setup for analyzing the comparative statics of changes in goods x and y. The two conditional budget constraints, $M_{xy}$ and $T_{xy}$, represent possible allocations of money and time expenditure between x and y, conditional on the optimal choice of the third good, $z^*$. The optimal choices of x and y, $x^*$ and $y^*$, are identified by the intersection of the two conditional constraints ; there is no need to introduce the preference map to find them. As opposed to the standard analysis, though, both conditional budgets depend on all parameters of the problem, so each will shift when any parameter changes.

### *2.1 Classifying Time- and Money-Intensive Goods*

As a preliminary to comparative statics, some relationships that prove important to the analysis of the two-constraint model are developed. The first is the notion of whether a good is relatively more time- or money-intensive in relation to other good(s), which is determined by the relative slopes of the time and money budget lines for pairs of goods. Good x is time-intensive relative to good y if the ratio of its time to money price is higher ; i.e., if

1. In general, if there were degrees of freedom for choosing $\hat{x}$ and $\hat{y}$ (as would be the case, for example, if there were only one constraint instead of two), they would also depend on $z^*$ directly as it affects the shape of the preference map, in addition to its indirect effect through M and T ; that is, $x = \hat{x}(p_x, p_y, t_x, t_y, z^*, M_{xy}, T_{xy})$ and $y = \hat{y}(p_x, p_y, t_x, t_y, z^*, M_{xy}, T_{xy})$. However, since the conditional budgets solve directly for $\hat{x}$ and $\hat{y}$, there is no opportunity for variations in z to affect the choice of x and y when the conditional budgets are fixed.

$$\frac{t_x}{p_x} > \frac{t_y}{p_y} \tag{9}$$

x is relatively more time-intensive than y[2]. Figure 1 is drawn so that x is time-intensive relative to y, in keeping with the interpretation of x as a recreation good and y and z as other non-recreation goods.

Two other characteristics of the time-intensive (x) and money-intensive (y) goods can be noted from Figure 1. Good x is referred to as *time-constrained,* because

$$\frac{M_{xy}}{p_x} > \frac{T_{xy}}{t_x}; \tag{10}$$

that is, the maximal quantity of x feasible under the (conditional) time budget is less than under the money budget, given the relative money and time prices of x. Similarly, good y is termed *money-constrained* because

$$\frac{T_{xy}}{t_y} > \frac{M_{xy}}{p_y}, \tag{11}$$

and the conditional money budget relative to money price is more binding on maximum y than is the conditional time budget.

## 3. CONDITIONS FOR THE TIME-INTENSIVE GOOD TO BE GIFFEN

By solving the two constraints (5) and (6), the conditional demands $\hat{x}$ and $\hat{y}$ can be written as

$$x = \hat{x}(p_x, p_y, t_x, t_y, M_{xy}, T_{xy}) = \frac{\frac{T_{xy}}{t_y} - \frac{M_{xy}}{p_y}}{\frac{t_x}{t_y} - \frac{p_x}{p_y}} \tag{12}$$

and

$$y = \hat{y}(p_x, p_y, t_x, t_y, M_{xy}, T_{xy}) = \frac{\frac{M_{xy}}{p_x} - \frac{T_{xy}}{t_x}}{\frac{p_y}{p_x} - \frac{t_y}{t_x}} \tag{13}$$

where the pre-conditioned optimal consumption of z enters through the conditional budgets $M_{xy} \equiv M - z^*$ and $T_{xy} \equiv T - t_z z^*$. Equations (9)-(11) imply that the numerators and denominators in (12) and (13) are all positive.

Consider a *ceteris paribus* change in $p_x$. The effects on consumption of x can be separated into a direct effect, holding z constant, and an indirect effect as $z^*$ adjusts given the new level of $p_x$ and both conditional budgets shift. The direct effect, from (12), is

2. Using the same logic to define the notion of relatively money-intensive, it follows immediately that if x is time-intensive relative to y, y is money-intensive relative to x, since (9) can also be written as $(p_y/t_y) > (p_x/t_x)$.

$$\left.\frac{\partial x}{\partial p_x}\right|_z = \frac{x/p_y}{D_y} > 0\,, \tag{14}$$

where $D_x \equiv (t_x/t_y - p_x/p_y) > 0$ is the denominator of the expression for x in (12), and is positive by (9). This is illustrated in Figure 2, where initial consumption is $(x_0, y_0)$ at the intersection of the conditional budgets $M^0_{xy}$ and $T^0_{xy}$. As the price of x falls, the direct effect is given by the counterclockwise rotation of the money budget from $M^0_{xy}$ to $M^*_{xy}$ ; consumption of x falls to $x_1$ while consumption of y increases to $y_1$. The intuition behind this is that as the price of the time-intensive good, x, increases, its relative time-intensiveness decreases, so that more is demanded. If the indirect effect is small relative to this direct effect, consumption of x will tend to increase with an increase in own price. The indirect effect, as changes in z* cause $M_{xy}$ and $T_{xy}$ to adjust, is

$$\left(\frac{\partial x}{\partial z}\cdot\frac{\partial z}{\partial p_x}\right) = \frac{\dfrac{-t_z\dfrac{\partial z}{\partial p_x}}{t_y} - \left(\dfrac{-\dfrac{\partial z}{\partial p_x}}{p_y}\right)}{D_x} = \frac{\left(\dfrac{1}{p_y} - \dfrac{t_z}{t_y}\right)\dfrac{\partial z}{\partial p_x}}{D_x}\,. \tag{15}$$

In Figure 2 this is the shift in budget lines from $M^*_{xy}$ and $T^0_{xy}$ to $M^1_{xy}$ and $T^1_{xy}$, respectively, which induces a further shift in consumption to $(x_2, y_2)$. Thus the indirect effect depends on whether x and z are Marshallian substitutes or complements (i.e., on the sign of $\partial z/\partial p_x$) and on whether z or y is the more time-intensive (i.e., on the sign of $(1/p_y - t_z/t_y)$. Recalling that $p_z \equiv 1$ and using (9), $(1/p_y - t_z/t_y)$ is positive (negative) if y is more (less) time-intensive than z. Thus, several sets of sufficient conditions for x to be Giffen can be identified from (14) and (15). They are

a) x and z are substitutes ($\partial z/\partial p_x > 0$) and y is more time-intensive than z

$$\frac{1}{p_y} - \frac{t_z}{t_y} > 0\,;$$

b) x and z are complements and z is more time-intensive than y ; or

c) z is strongly separable from x and y in the preference function ($\partial z / \partial p_x = 0$) ; or

d) y and z are equally time-intensive.

If either (a) or (b) holds, both the direct and indirect effects of the change in $p_x$ are positive, reinforcing the Giffen effect ; while for (c) and (d), the indirect effect is zero.

The time-intensiveness conditions are easily checked in applied studies from knowledge of the parameters (prices and budgets) an individual faces and their optimal consumption quantities [3]. The substitution relationship between x and z is a matter of conjecture, but a reasonable hypothesis would be that x and z are substitutes. The same intuition that explains the positive own-price response through the direct effect for x also suggests this. The increase in money price of the time-intensive good x also decreases the money-intensiveness of the money-intensive good, z ; therefore one could expect an increase in z, implying $\partial z / \partial p_x > 0$.

Condition (c) is a special case of the general analysis where z doesn't change as parameters concerning x and y change ; this corresponds to the two-good analysis of the GK paper. Condition (d) is another special case where changes in expenditures on z and y exactly offset each other as the price of x changes, so the indirect effect is zero and x is Giffen because of the positive direct effect. This corresponds to the comparative statics analysis of the three-good case in the GK paper[4]. While restrictive, this condition is useful in identifying generic commodities likely to exhibit Giffen behavior

3. In particular, because of the normalization over $p_z$, $p_z = 1$ and $t_z = (T - T_{xy})/(M - M_{xy})$ ; these can be compared with $p_y$ and $t_y$ to determine whether y or z is more time-intensive.

such as outdoor recreation, which is particularly time-intensive. For example, if all other goods are of approximately equal time-intensiveness, condition (d) indicates that outdoor recreation will be a Giffen good regardless of its substitution relationships with those goods, because of its greater time-intensiveness.

### *3.1 Observable Sufficient Conditions for x to be Giffen*

Directly observable, and weaker, sufficient conditions for x to be Giffen can be expressed by taking account of relative magnitudes of both the direct and indirect effects. This eliminates the need to appeal to intuition about the changes in the third good z as prices of x or y change.

The largest possible reduction in x through the indirect effect is $x^{min} - x$, where x is the initial quantity and $x^{min}$ is the lowest possible consumption of x given prevailing relative prices and budgets. Thus, we seek the conditions for which

$$\frac{x/p_y}{D_x} + (x^{min} - x) > 0 ; \tag{16}$$

and if these hold, x is necessarily Giffen.

Note from (16) that if $(1 / p_y) > D_x$ x is necessarily Giffen, since quantities of all goods are taken to be positive initially and $x^{min}$ is non-negative[5]. A little algebraic manipulation reveals that this is an easily checked condition : $(1/p_y) > D_x$ implies that

$$t_x/p_x < (1 + 1/p_x)\, t_y/p_y . \tag{17}$$

This is the condition on relative prices implicitly assumed by GK when they graphically illustrated the three good case and argued that "consumption of potatoes necessarily rises" when the price of potatoes increases (p. 186). The remaining case to be investigated, therefore, is where $(1/p_y) < D_x$.

The value of $x^{min}$ is determined by, and will vary with, the relative prices and the budget constraints for the problem. Consistent with the earlier discussion, consider, for example, three goods for which the following relative prices and budgets apply :

$$\begin{cases} \text{x is time constrained } (M/p_x > T/t_x) ; \\ \text{y and z are money-constrained } (M/p_y > T/t_y,\ M > T/t_z) ; \text{ and} \\ t_x/p_x > t_y/p_y > t_z . \end{cases} \tag{18}$$

Using (1) and (2) to write y and z parametrically in terms of x,

$$z = \frac{t_y\, p_y \left\{ \frac{M}{p_y} - \frac{T}{t_y} \right\} - \left\{ \frac{t_y}{p_y} - \frac{t_x}{p_x} \right\} p_x\, x}{t_z \{t_y/t_z - p_y\}} \qquad \begin{matrix} \{-\} \quad \{-\} \\ \\ \{+\} \end{matrix} \tag{19}$$

and the signs of the terms, given in braces, are implied by conditions (18). The signs on the numerator of (19) imply that a minimum for x is given by z = 0 :

4. Though they don't address the issue directly, for GK's statement that when the price of potatoes increases, "consumption of potatoes necessarily rises" (p. 186) to be correct without qualification requires that there be no change in potato consumption as the consumer substitutes among meat and their third good (x in their analysis) along the line segment AD. They are referring to the direct effect only in this passage.

5. This can also be expressed as $t_x /t_y < p_x/p_y + 1/p_y$ ; but also, by assumption $P_x /p_y < t_x/t_y$, so the two conditions together are $p_x /p_y < t_x /t_y < /p_x\ p_y + 1/p_y$. Thus, if x is only slightly more time-intensive than y, x is necessarily Giffen for this case.

$$x^{min} = \frac{t_y p_y \left\{ \frac{T}{t_y} - \frac{M}{p_y} \right\}}{p_x \left\{ \frac{t_x}{p_x} - \frac{t_y}{p_y} \right\}} \tag{20}$$

Using (20) in (16), with some rearrangement, gives

$$x \frac{(1/p_y) - D_x}{D_x} > - \frac{p_y \left\{ \frac{T}{t_y} - \frac{M}{p_y} \right\}}{D_x},$$

which leads to an upper bound on the quantity of x that implies x is Giffen :

$$x < \frac{(p_y / t_y)T - M}{D_x - 1/p_y} \quad \text{when} \quad D_x - 1/p_y > 0. \tag{21}$$

Conditions (17), (18), and (21) are easily checked from data on relative prices and budgets, and eliminate the need for conjecture about the relationship between x and the third good z. In this particular case, only prices of the two primary goods of interest (x and y) alone are needed. Conditions such as (17) and (21) will vary with the actual price relationships among goods, but are easily derived. Table 1 presents a summary of observable conditions which imply that a good is Giffen with respect to money price changes.

### *3.2 Outdoor Recreation As a Potential Giffen Good*

The preceding analysis demonstrates that time-intensive goods seem especially likely to exhibit Giffen behavior with respect to money price changes, when both constraints bind[6]. One of the key features which distinguishes outdoor recreation from other goods is the prominence of time in decisions concerning its consumption. Indeed, its consumption is often denominated in time units (days or hours spent at a site), and plays an important role in its cost as well because outdoor recreation is typically consumed at sites distant from the home. Thus, trips to engage in outdoor recreation (the x in the present model) usually require a substantially higher commitment of time relative to money than do other consumption goods, so outdoor recreation is relatively time-intensive.

A couple of examples of the model's predictions will help to illustrate the point. Suppose that x is an outdoor recreation activity such as a day hike in the nearby woods or mountains, or a day at the park downtown ; this is a relatively time-intensive activity. Let y and z be indoor activities such as housework and indoor recreation. Because y and z both require housing services, they are approximately equal in money-intensiveness and are more money-intensive (less time-intensive) than x. Because of their equal money-intensiveness, the indirect effect of a change in $p_x$ is zero because $(1/p_y - t_z/t_y)$ in (15) is zero ; thus an increase in the money price of the outdoor recreation (because, say, of an increase in gasoline prices) should, all else equal, lead to an increase in trips to the woods or local parks.

As a second example, suppose that x and y are two types of outdoor recreation activities, with x representing trips to the beach and y being a relatively expensive outdoor activity such as hot air ballooning, glider flying, or backcountry skiing ; z is consumption of all other goods. Beach-going is the good x in the analysis since it is more time-intensive than ballooning (y), and both are more time-intensive than z. It is likely that x and z are substitutes, since an increase in the price of a beach visit reduces the money-intensiveness of z relative to x and leads to more of z being consumed.

6. Likewise, the money-intensive good is especially likely to have a positive response to changes in its time price, though this effect has not traditionally been labeled "Giffen."

According to condition (a) in section II, the amount of beachgoing one does will also increase as the money price of a beach visit increases[7] ; the quantity of ballooning will decrease and purchases of all other goods will increase.

## 4. WHY HASN'T A GIFFEN RECREATION GOOD BEEN FOUND ?

The foregoing analysis shows that time-intensive goods appear to be especially susceptible to being Giffen goods ; that in response to an increase in own money-price (own time-price and all else constant), an increase in consumption should be observed for at least some time-intensive goods. Given this bold prediction, and the fact that outdoor recreation offers a prominent example of time-intensive goods, one might well ask, Why it is that no evidence of Giffen behavior in outdoor recreation has been reported ? [7]

One reason is that no recreation demand studies in the empirical literature have yet fully implemented the demand models implied by the choice problem (3)[8]. While recent empirical recreation demand models are more comprehensive and sophisticated than those in earlier studies, data limitations have usually prevented the estimation of separate time and money price and time and money budget effects on the demand for recreation.

A substantial literature recognizes that omission of time prices from estimated outdoor recreation demand functions will lead to a downward bias in the estimated money price parameter. This has two consequences, the first of which is widely recognized : that consumer's surplus associated with the good will be underestimated (Clawson ; Knetsch ; Cesario).

The second consequence is of particular interest to the question of uncovering Giffen behavior for recreation goods. If x is a Giffen good, its true money price coefficient is positive. However, the downward bias in the estimated money price coefficient will reduce its statistical significance, or even change its sign (from positive to negative) ; the effect, in either case, will be to mask the Giffen behavior.

The recognition of the first consequence of omitting time parameters has led to a number of suggestions about how to value travel time, in order to collapse the two-constraint problem into a standard, one constraint problem. This usually results in an empirical specification of the following type :

$$x_i = \hat{\alpha} + \hat{\beta}(p_i + k w_i t_i) + \hat{\delta} M_i + v_i , \tag{22}$$

where $w_i$ is the individual's wage rate and k is a fraction between 0 and 1 (Cesario ; McConnell and Strand ; Smith et al. SEJ ; Bockstael et al.). The justification for these specifications is that the individual is making a labor-leisure choice which identifies an observable exogenous parameter as the value of time.

These specifications are essentially incapable of testing for Giffen behavior because they impose the a priori assumption that the own-time price and own-money price effects are of the same (usually negative) sign. By differentiating (12) with respect to $t_x$, it can be seen that if x is Giffen with respect to changes in $p_x$, it will most likely have opposite signs on the money- and time-price coefficients : positive for the former and negative for the latter. Thus, imposing the assumption in (22) that time and money price have the same sign (through the common $\beta$ ) virtually rules out the prospect of finding Giffen behavior.

To sum up, the reason no empirical evidence of Giffen recreation goods has yet been found is that existing empirical estimates of recreation demand are based on estimation frameworks that, because of omitted variables or a priori reasoning, are not sufficiently flexible to enable the behavior to be observed.

7. The only examples we have found in the published literature of positive own-price elasticities is in the paper by Smith et al., who report positive own-price elasticities for two of 22 ordinary least squares estimates of recreation demand models ; neither is statistically significant at the 5 % level. The authors do not suggest that Giffen behavior is responsible for these results.

8. The best empirical study to date is the work of Bockstael, Strand, and Hanemann, who estimate utility-theoretic demand functions for recreation that depend on both time and money budget parameters. They obtained a significant negative own-time price effect, which is expected for time-intensive goods (see (16)), and a negative (but very small in magnitude) own-money price effect which, in their specification, is tied to the (statistically insignificant) money income effect. Because three parameters are estimated for the two price and two money effects, their study does not appear to offer any evidence one way or the other regarding possible Giffen behavior.

## 5. CONCLUSIONS

Giffen behavior, i.e., an increase in quantity of a good demanded in response to an increase in its money price, may well be more widespread than is currently believed, if only we know where and how to look for it. To make this point, we develop a general three-good model where choices are made subject to money and time constraints, and show how the optimal choices can be conveniently represented graphically in two-space by analyzing an equivalent conditional choice problem. We develop easily-checked sufficient conditions for a good to be Giffen, involving relative time-intensiveness and budgets.

The intuition behind the results lies in the notion of time- and money-intensiveness : as the money price of the time-intensive good increases, its *time-intensiveness decreases,* and this tends through the direct effect to lead to a substitution toward the time-intensive good to achieve the highest possible level of utility. Analogously, increases in the own time-price of the money-intensive good leads to an increase in its consumption : a Giffen-like phenomenon with respect to time.

Given the suggestion that time-intensive goods such as outdoor recreation may be prone to Giffen behavior, the question of empirical verification arises. Virtually no published study has come up with a positive own-money price coefficient, with a couple of statistically-insignificant exceptions. However, the specifications estimated in existing recreation demand studies are not capable of reflecting such behavior, for reasons either of variable omission or a priori judgments about the nature of the individual's decision problem.

Perhaps the framework and results in this paper will stimulate a closer look at the empirical possibilities for finding Giffen behavior in recreation demand and other commodities for which choice is made subject to multiple constraints.

ABSTRACT

*In principle, a competitive economy allocates its resources among conflicting uses such that the marginal net return to any given resource is equal across all uses of that resource. For a fishery resource, this principle has been adopted as a norm against which to judge government policy. While the notion has not gone unchallenged, economists have, largely, accepted its basic premise and, indeed, have devoted considerable effort to the question of how to measure net economic value. Measurement problems have been particularly troublesome where markets do not exist and where externalities are large. In the case of the fishery, for example, there are both conceptual difficulties and corresponding empirical problems. These stem principally from the "open-access" nature of the fishery and the "non-market" nature of the good/service combination produced and consumed in the recreational fishery.*

*These issues are complicated considerably when it is recognized that both inputs and outputs in several fishery sectors are traded in international markets. Not only do measurement problems increase but one is faced with how to make allocation decisions when resulting additions to or reductions in economic value are realized in foreign countries.*

*This paper advances three arguments :*

*i) Events in international markets can have enormous consequences in domestic markets. Attempts to implement the equi-marginal rule may, therefore, require reallocation in response to those events.*

*ii) Failure to recognize interdependencies between international trade policy and resource management may lead to unexpected results.*

* This paper draws heavily on a draft manuscript prepared for A.T. Kearney. The authors are grateful to Steve Edwards for helpful comments on that draft. Discussions with Grant Thompson, Jim Hastie, Lewis Queirolo, and Dave Colpo have also been valuable. Partial support for the research reported here has been provided by the Cooperative State Research Service, U.S. Department of Agriculture (Agreement No. 92-34276-7140) and by the OSU Sea Grant program.

*iii) Whether or not the equi-marginal principle is adopted by fishery managers, it may offer guidance for potentially useful research. For fishery managers, this suggests a better understanding of the markets into which the resources they manage move.*

## 1. INTRODUCTION

According to a generally-accepted principle of economics, a competitive economy allocates its resources among conflicting uses such that the marginal net return to any given resource is equal across all uses of that resource. In welfare economics, this principle has been adopted as a norm against which to judge — or prescribe — government policy. For example, in the case of a fishery resource, Edwards argues that "in order to maximize the total net economic value from using fish for food and sport, an allocation must equate *marginal* net economic values from each conflicting use of the fish stock." (italics in original) (Edwards, p. 20). While use of the equi-marginal principle as the sole prescriptive tool for resource management has not gone unchallenged (Bromley), economists have, largely, accepted its basic premise and, indeed, have devoted considerable effort to the question of how to measure net economic value. Measurement problems have been particularly troublesome where markets do not exist and where externalities are large. In the case of the fishery, for example, there are both conceptual difficulties (e.g., Bockstael and Strand ; Just, et al., append. B) and corresponding empirical problems (Bergstrom, et al.). These stem principally from the "open-access" nature of the fishery — especially, but not only, the commercial sector — and the "non-market" nature of the good/service combination produced and consumed in the recreational fishery.

These issues are complicated considerably when it is recognized that both inputs and outputs in several fishery sectors are traded in international markets. Not only do measurement problems increase but one is faced with how to make allocation decisions when resulting additions to or reductions in economic value are realized in foreign countries.

This paper advances three arguments :

iv) Events in international markets can have enormous consequences in domestic markets and, hence, may importantly affect the relationship between fish landings and marginal net economic value. Attempts to implement the equi-marginal rule may, therefore, require re-allocation in response to those events.

v) Failure to recognize interdependencies between international trade policy and resource management may lead to unexpected results. Collaboration between fishery managers and trade policymakers may reduce this problem.

vi) Whether or not the equi-marginal principle, as a norm, is adopted by fishery managers, who must consider political and other "non-economic" criteria, assuming that it does, at least as a first approximation, may offer guidance for potentially useful research.

None of these arguments sounds particularly profound or insightful. The principal contribution of the paper, however, is to suggest a framework within which trade and natural resource issues can be considered simultaneously.

## 2.. THE MODEL

We begin with a diagram, first proposed by Schaeffer, depicting the growth of a stock of fish over time. In Figure 1, the size of the stock, measured on the vertical axis, follows a sigmoid curve, increasing initially at an increasing rate, followed by a growth pattern along which the stock approaches a maximum, F*, (the "carrying capacity" of the stock's environment) asymptotically. This is only one of several models of how a fish stock grows but it is commonly used by both biologists and fishery economists and, in any event, provides all of the ingredients needed for the present discussion.

Bioeconomic models begin with a formulation such as that of Figure 1. From there policy makers can design "socially optimum" exploitation strategies : fishing patterns over time that maximize the net present value of the resource (Clark). These optima are highly sensitive to assumptions about the relevant interest rate, fishing costs and demand patterns. Recent extensions have examined the issue in the context of a multi-species fishery and have introduced elements of uncertainty (e.g., Kirkley and Strand).

The model of this paper is offered in a similar spirit. In particular, the early bioeconomic model is modified to permit the coexistence of both a commercial and a recreational fishery on a given stock and to allow sales of the commercially-harvested fish in both domestic and international markets. In the paper we make a simple point: occurrences in international markets may place enormous pressure on fishery managers to change allocations to the recreational sector. This is not an unexpected result, although there are a few surprises en route to its development.

The argument can be most easily demonstrated through expanding on an analytical model developed by McInerney and later used by Just, et al. Its highly simplified assumptions permit the use of two-dimensional graphs and allow the simultaneous consideration of market and resource management issues. Use of the model in any practical setting would, of course, require much more complexity than is employed here. Nonetheless, the model does generate useful insights and suggests testable hypotheses.

The model looks at only two time periods. This means that, from the many dates represented on the horizontal axis in Figure 1, only dates $t_0$ and $t_1$ are considered. That is, in the first period, the economy has the option of harvesting all, some, or none of the stock, whose size then is $F_0$. Any amount of $F_0$ not harvested can grow at the rate g (the slope of the line connecting $F_0$ to $F_1$ in Figure 1 is $1 + g$) and becomes available for harvest during the second time period. Looking at the issue this way obviates the necessity of distinguishing between stocks and flows : stocks are reduced by harvest and increased by growth, both flow measures. The analysis begins with only a commercial fishery and a domestic market.

Figure 2 is a four-quadrant diagram depicting supply and demand conditions for fish from this stock in each of the two time periods. In the upper right quadrant, $MCB_0$ measures the marginal social benefits associated with different levels of commercial harvest during the current period, $t_0$. It can be thought of as a "general equilibrium" demand curve at the ex-vessel level, assuming no externalities in the markets for fish, other than those reflected in prices. The area under this curve embraces all of the consumer and producer surpluses along the market channel to the final consumer, except for the producer surplus associated with commercial harvesting this period. This last surplus is reflected in $MXC_0$, which is the marginal cost of harvesting ("extraction") in the current period. It represents the additional costs of harvesting associated with catching larger and larger quantities of fish, out to a maximum harvest of $F_0$, the stock size in $t_0$. It has a positive slope, reflecting the presence of "highliners" in the commercial fleet and the decline in the catch per unit effort with increased harvests.

The curve labeled $AXC_0$ depicts the average costs that fishermen would incur during the current period, at various harvest levels. This curve does not appear in the original McInerney and Just, et al. diagrams, presumably because those authors focus on the user cost issue and not the short run "open access" phenomenon. Curve $AXC_0$ is simply the "average" curve corresponding to $MXC_0$.

At this point it is worthwhile commenting on the slope of the $MCB_0$ curve. In the case of many fish stocks it may be appropriate to think of prices (at all levels of the market channel) as being independent of the level of harvest from those stocks. That is, a given stock may make such a small contribution to the total supply of the species that the volume harvested from that stock has no effect on market price. In that case the $MCB_0$ curve will contain no consumer surplus and its slope will reflect only whatever producer surpluses accrue along the marketing channel.

However, in these days of the "niche-market," such an assumption may be incorrect. In the case of west coast salmon, for example, there appear to be numerous such markets. Buyers of salmon for restaurants in Southern California seldom know the origin of the fish they purchase, especially if the fishing occurs in Alaskan waters, but they demand a consistent quality that processors can supply only from selected runs. Similarly, Columbia River gillnetters report a premium for their fish by delivering directly to smaller fish markets in the Portland, Oregon, area. Some restaurants in the Puget Sound include on their menus the names of the fishermen from whom they buy salmon. Thus, even where the management question pertains to individual stocks, it may not be inappropriate to assume negatively-sloped final demand curves.

Return to Figure 2. In the lower left quadrant, $MCB_1^*$ shows the marginal social benefits of harvesting and marketing different quantities of fish in the second period, $t_1$ ; $MXC_1^*$ shows the marginal extraction costs for those fish harvested in $t_1$ ; and $AXC_1^*$ is the corresponding average harvesting cost. In the upper right quadrant $F_0$ is the size of the fish stock at the beginning of time period $t_0$. If none of $F_0$ is utilized in $t_0$ the stock can grow to $(1 + g)F_0$ by time $t_1$. For ease of presentation, g is assumed to be stock (density)-independent, although the analysis does not rely on this. Thus the line from $F_0$ to $(1 + g)F_0$ in the lower right quadrant represents alternative combinations of $t_0$ and $t_1$ harvests available from the initial stock.

The line in the upper left quadrant has the slope $(1 + g)/(1 + r)$, where r is the appropriate social discount rate between the two time periods. Thus $MCB_1$ in the upper right quadrant is derived "by deflating the marginal social benefit... in the lower left quadrant by the social discount rate of r but then inflating by a rate of g because nonuse of 1 quantity unit at time $t_0$ supports consumption of $1 + g$ units at time $t_1$" (Just, et al., p. 323). The marginal and average extraction cost curves, $MXC_1$ and $AXC_1$, are derived similarly. Note that these curves are drawn independently of the stock size in $t_0$. This is not an inappropriate assumption for processing and marketing costs. It is questionable in the case of fishing costs, however, which are likely to rise as the stock size falls.

Note that no consideration is given yet to the recreational fishery. This is introduced below, as is the international market.

At the "open access" equilibrium in the first period, price $p_0$ would prevail and $\underline{f}_0$ units of fish would be harvested. This is where fishing effort is employed to the point at which the average cost of fish equals the ex-vessel price of fish. Similarly, the open access equilibrium in the second period would yield $p_1$ and $F_0 - \underline{f}_1$, measured in $t_0$ units, (or p measured in $t_1$ units) requiring that no more than $f_1$ be utilized this period. Thus, the available stock of fish in $t_0$, $F_0$, does not permit realization of both open access equilibria. If $\underline{f}_0$ units of fish were harvested in this period, only $(F_0 - \underline{f}_0)$ units would remain to grow in the next period to $f_1^*$.

To correct this externality, the equi-marginal principle discussed earlier is applied, with all costs and revenues being expressed in current dollars and quantities expressed in terms of the available stock of fish at the beginning of the first period. The "social optimum" is obtained by equating the marginal net benefit curves, $MNCB_0$ and $MNCB_1$, for the two periods. These curves are derived as the vertical differences between their respective MCB and MXC curves and express, in current period dollars, the incremental net benefits, after accounting for all costs but including any consumer and producer surpluses along the market channel, associated with different levels of harvest. As depicted, the "social optimum" is found at harvest levels of $f_0^*$ and $f_1^*$, with corresponding prices of $P_0^*$ and $P_1^*$ for the first and second periods, respectively. (A more complete model would, of course, consider more than two periods.)

## 3. INCLUDING A RECREATIONAL FISHING SECTOR

This model can be expanded to include consideration of a recreational fishery. In the following discussion, however, the distinction between the MXC and AXC curves is dropped. While the distinction is important, it is not needed to make the intended points and dropping it simplifies the diagrams enormously. Further, the distinction is not used by either McInerney or Just, et al. Thus we move from considering "open access" equilibria to considering "free market" equilibria in which only current benefits and costs are considered (i.e., user costs are ignored) but where other fishing externalities are not considered explicitly. Such an equilibrium is found at the intersection of the benefit and cost curves for the current period.

Figure 3, then, retains the MCB and MXC curves of Figure 2 and adds three new curves : $MNRB_0$, MNRB and $MNRB_1$. The first of these is the "general equilibrium demand" for recreational fishing on this fish stock in the current time period, net of the cost of fishing. Curve MNRB is the counterpart curve for recreational fishing that occurs in $t_1$ , with $MNRB_1$ being its translation into current period dollars and fish stocks. These, then, are "marginal net recreational benefits" curves. By using them, some elements of the open access nature of the recreational fishery are ignored, as in the commercial fishery. Nonetheless, the primary insights are retained. One significant limitation of the analysis, however, is the assumption of independence of the commercial and recreational fishing sectors in both demand and cost of harvest. Recognizing such interdependencies would be important for empirical work in any fishery but would add unnecessary complication to this discussion.

If the fishery is not managed to obtain the "social optimum," the "free market" commercial catch in this period is $f_0$ (determined by the intersect of $MXC_0$ and $MCB_0$). Now, however, there is also a current period harvest of $\underline{Rf}_0$ in the recreational fishery. At these levels, an even more insufficient stock of fish is left for harvest by the two user groups in $t_1$.

With fishery management, the social optimum is achieved at the intersection of $MNV_0$ and $MNV_1$, where each MNV curve is the horizontal sum of its corresponding MNRB and MNCB curves. At this point the "marginal net economic values from each conflicting use of the fish stock" are equal (Edwards, p. 53). To achieve this result, the fishery managers

will design instruments that result in a total harvest of $f_0^*$ in $t_0$. This consists of $f_0$ units of fish being harvested by the commercial fleet at the price of $P_0^{'}$ and a recreational catch of $Rf_0$. This permits a total harvest of $f_1^{''}$ units of fish in $t_1$, consisting of a commercial harvest of $f_1^*$ units at the price of $P_1$ in $t_0$ dollars (or $P_1^*$ in $t_1$ dollars) and a recreational catch of $Rf_1^*$.

This result will change in response to a change in the interest rate, r. This period's harvest, both commercial and recreational, are favored with a higher r. Similarly, if g were to increase or if $F_0$ were larger — perhaps through fishery enhancement programs — more fish would be available. The cost of programs that increased either g or $F_0$ would have to be considered in deriving the new optimum. And, of course, any change in a variable that affects one or more of the marginal benefit and marginal cost curves may also shift that optimum.

Expanded by more appropriate representations of the relevant biological and economic relationships, this kind of model underlies the goals articulated by economists with a normative orientation. Much of the fishery economics literature, then, has focused on how well various policy instruments can do to realize these goals. Tax schemes, subsidy schemes, various quota arrangements, and limitations on inputs are among the policy arrangements considered and, in some cases, implemented.

One set of policy instruments has, in general, not been considered : those that focus away from the ex-vessel level and on conditions in the markets for seafood (or other fish/shellfish product) elsewhere in the market channel, including the wholesale and retail levels. If there are monopoly or monopsony elements at one or more of these levels and if this is not recognized in the design of management policies, the desired objective may be far from realized. With some exceptions (e.g., Bradley ; Capalbo and Howitt ; Clark and Munro) this issue has received little attention in the literature. Perhaps the reason for this is that, in many cases, as indicated above, a given stock of fish supplies only a small portion of a market so that price is invariant with respect to the level of harvest on that stock. Thus, no matter what policy is adopted by fishery managers, it is assumed that there will be no effect on price, irrespective of the structure of the market.

For many fishery management decisions, however, such an assumption cannot be sustained. Because of the contribution of Alaska pollock to world groundfish, including surimi, markets, decisions in that fishery could affect prices and the product forms into which the fish is processed and marketed. When allocation decisions among gear types and user groups affect the entire West Coast salmon fishery, market effects may be significant. "Market niche" arguments are presented above. In all such cases market structure and pricing behavior along the market channel will affect the nature of the MCB curves and could complicate their estimation.

Thus, decisions at various stages of the market channel may change the "optimal" levels of harvest and allocation among gear types and user groups. One particular set of decisions merits attention because of the large potential impacts on resource utilization and because such decisions are often made with no consideration of those impacts. These decisions fall under the general heading of "international trade policy." Policies designed to promote exports or to restrict imports may have consequences for resource use that steer utilization away from its "optimal" level. Consequently, resource managers may find that their policies run counter to those adopted by trade policy-makers. This is an issue that may be especially important to coastal nations that, since extending their fishery jurisdiction, find themselves in possession of a resource capable of generating significant benefits through expanded exports.

## 4. INTERNATIONAL MARKETS

Elements of the interdependencies between trade policy and resource utilization are depicted in Figure 4. The principal difference between this figure and Figure 3 is that a trade sector has been added. In the upper right quadrant the needed (appropriately transformed) curves from the lower left quadrant are shown. The trade sector is represented by (1) the perfectly price-elastic line emanating from $p_{w0}$ in the upper right quadrant, reflecting the opportunity to export F at that price in the current period and (2) the perfectly price-elastic line emanating from $p_{w1}$ in the lower left quadrant, reflecting the opportunity to export fish at that price in the next period. The "export demand" curves are assumed to be perfectly price-elastic under the assumption that fish from this stock compete with so many others in international markets that they have no effect on price. As suggested above, this assumption is unrealistic for many managed fisheries in the U.S. and, thus, it is dropped in the later discussion.

The addition of export opportunities can change both the temporal and user group allocations. In the case depicted, the new optimum is found where the AMNV curves for the two periods intersect in the upper right quadrant. These "aggregate marginal net value" curves are the MNV curves augmented by the benefits that can be realized by exports. As before, both curves are expressed in terms of current period dollars and fish stocks.

The socially optimum levels of the model's variables in $t_0$ and $t_1$ are respectively shown as $\hat{f}_0$, $\hat{f}_1$ for total harvest, as $f_0^{\#}$, $f_1^{\#}$ for the commercial harvest, as $rf_0^{\#}$, $rf_1^{\#}$ for the recreational catch, as $X_0^{\#}$, $X_1^{\#}$ for total domestic utilization, and as $(\hat{f}_0 - X_0^{\#})$, $(\hat{f}_1 - X_1^{\#})$ for exports.

Note that the desired commercial harvest level in the current period, in the absence of management would be at a higher level than with management ($f_0^0$). Even without, when added to the desired recreational harvest, it exceeds the total stock of fish available in $t_0$ and, thus, nothing is left for period $t_1$. With explicit consideration of the stock and crowding externalities (so that the open access equilibrium would be determined by average, not marginal, cost curves) the divergence would be even more exaggerated.

Now consider the impact of an export enhancement program imposed in $t_0$ only on the optimum allocation. The results are depicted in Figure 5, where "s" is a subsidy per unit of F exported. The "social optimum" is obtained at the intersection of the $AMNV'_0$ and $AMNV_1$ curves, where the (') indicates that the $AMNV_0$ curve is adjusted to reflect the reduction in social benefits that accompany the subsidy program. For the particular circumstances depicted, the optimal allocation does not change. While exporters realize a gain in their incomes, domestic consumers experience losses in consumer surplus. Beyond this, payment of the subsidy imposes a welfare loss on the taxpayers of this exporting country in $t_0$.

If the $AMNV_0$ curve was not adjusted to reflect these losses, and if, instead, fishery managers used the subsidized export price in calculating domestic social benefits, the resulting "optimum" corresponding to the intersection of $AMNV_0$ and $AMNV_1$ could significantly deviate from that described in the previous paragraph. Note, also, that the export enhancement program exacerbates the "open access" problem in an unmanaged fishery ($f_0^{\#}$). Indeed, in this case, the activities of commercial harvesters in the current period would leave nothing for harvesting during the later period.

On the other hand, this diagrammatic presentation also suggests that trade policy can be used to augment fishery management. If a country is an importer of F or of close substitutes for F, subsidizing those imports should reduce the demand from domestic stocks, at least for the commercial product. In the case of an unmanaged fishery, the result could be a net increase in net social welfare, even when the cost of the subsidy is included. Whether or not there will be such an increase is, for any particular fishery, an empirical question. In any event, it is clear that there are interdependencies between trade policy and fishery management policy. An understanding of the policies of one sector by the policy-makers in the other should reduce frustrated expectations for both.

Similarly, there are good reasons for fishery managers to be sensitive to changes in the policies of trading partners. A country that subsidizes its exports of seafood may generate results comparable to those of resource management in the importing country. A similar role may be played by countries that restrict imports of seafood from exporters. It is interesting that, for goods produced under conditions of strong property rights and few externalities (e.g., agricultural products), such practices by trading partners would be viewed as operating against domestic interests. In the case of an unmanaged resource at home — or one that is costly to manage — they may, instead, serve to benefit the country against which the policies are, or are intended to be, directed. In any event, fishery managers can certainly justify keeping informed of developments in the international arena.

## 5. DISTRIBUTION OF GAINS

Suppose the fishery in question is an important supplier of fish in the international market and that, therefore, the export demand, instead of being perfectly price-elastic, as in Figure 4, is negatively sloped. How would this affect the socially optimum allocation of fish between periods and among user groups ? At first glance, it would appear that the added dimension could be treated in a fashion similar to the situation in which the domestic consumer demand is negatively-sloped. Indeed Edwards provides a clear demonstration of how this can be accomplished, illustrating how consumer surplus can be accommodated in a general equilibrium ex-vessel demand equation (Edwards, Appendix C).

However, such surplus is assumed to accrue to domestic, not foreign, consumers. In international trade theory, efficient resource allocation calls for maximum global benefits, not distinguishing among producers and consumers with respect to place of residence. However, if a country is large enough in world markets to affect its terms of trade, it may be possible to devise an "optimum tariff" that generates net benefits to the importing country. Similarly, a policy that gives zero weight to the well-being of foreign consumers may yield a domestic "social optimum" similar to that resulting from the assumption that the exporting country was practicing monopoly pricing (although in a many-commodity world, this would have to be modified to include the role of "surpluses" in other markets and the possibility of retaliation by trading partners, either directly or indirectly).

In their discussion of general equilibrium demand curves in the presence of international markets, Just et al. suggest treating world prices of traded goods as exogenous variables, indicating that "...conditioning of supply and demand estimates on external prices of traded goods will result in measuring equilibrium welfare for only the constituents of the economy in question" (Just et al., p. 208). In the case of a negatively-sloped export demand curve, however, this begs the question, since the world price itself is affected by the domestic allocation policy. Once again, it is clear that trade policy decisions and resource allocation decisions are not independent.

In addition, some inputs used by the fishing industry may be imported and, thus, associated producer surpluses may leave the country. How are such surpluses to "count" in calculating the social optimum ? And the same question arises when substitutes for the domestic product are imported from abroad and when the domestic country is a significant importer of these substitutes, able to affect world prices by its actions.

Finally, it must be observed that many fishery management decisions are made with regional interests in mind. Thus, the above discussion of the role of international markets could be extended to include the role of consumer and producer surpluses that accrue to individuals outside of the management region. In such cases, again, knowledge of markets may be helpful to fishery managers.

## 6. INCREMENTAL DECISION-MAKING

The discussion to this point has dealt exclusively with "either/or" decisions : either the fishery is managed to be at the "social optimum" or it is not. In fact, most fishery management decision-making processes are of a much more incremental nature ; that is, most decisions are designed to adjust seasons, landings, etc., in response to changing conditions, such as health of the stock, oceanographic conditions, and the like. In such cases, it is tempting to argue that because effects along the market channel are likely to be small they can be ignored. Ex-vessel prices, then, can be assumed to be constant and costs and benefits of management changes can be estimated by calculating their likely impacts on revenues to commercial fishermen and recreational benefits to sports fishermen and women.

A difficulty with this argument is that decisions along the market channel are also made "at the margin," so that even small changes can have market impacts. This is particularly true in the case of those fisheries in which an important product is fresh seafood. Management decisions that affect the stability of supply may dramatically affect prices, especially if there are seasonal patterns in consumer demand. Recent analysis of the Japanese market for seafood, an important market for U.S. exports, suggests that there is a significant seasonal component to demand there.

Similarly, allocation among gear types may importantly determine product form and the market segments to which the product travels. For the Pacific Fishery Management Council of the U.S., this has been a central issue in allocating coho and chinook salmon among troll and net fishermen.

Many management decisions are made in response to changes in biological conditions. Some of these, including restrictions on mesh size or on location of fishing activity, may determine sizes of individual fish supplied to the market and, in the extreme, may lead to supplying those sizes and qualities demanded least, with corresponding effects on prices.

These are a few examples of how incremental management decisions in a fishery may have significant marketing impacts that importantly affect the economic well-being of the various user groups. Analogously, it is possible for relatively "small" marketing decisions to have enormous resource use impacts and, hence, to create a need for changing allocation decisions by fishery managers. A famous U.S. example is that of a popular Louisiana restaurant whose chef developed a recipe for blackened redfish that enormously increased the demand for red drum from the Gulf of Mexico. The result was tremendous pressure on red drum stocks that led to indefinite closure of the commercial offshore fishery.

Clearly, even for incremental changes, decisions made at the various market levels, including international markets, may have significant impacts on variables of interest to fishery managers. Similarly, adjustments in fishery management that appear to be relatively minor may have market impacts which, in turn, feed back to those variables — especially, prices — of interest to fishery managers. Application of the equi-marginal principles outlined above provides guidance regarding the information it is necessary to have in order to predict the likely consequences of management/policy changes.

## 7. RECOMMENDATIONS

This reasoning leads to three sets of recommendations :

i) Fishery managers may benefit from being aware of what is occurring in the markets for the resources they are managing. This includes an understanding of factors affecting supply and demand conditions for seafoods and other products produced from the relevant fish stocks, as well as an appreciation of the institutional/market structure within which market decisions are made.

ii) Fishery managers and those involved in trade (and, perhaps domestic market) policy may benefit from working together as they design and use management/policy instruments. Such collaboration may reduce the incidence of unexpected consequences. Similar benefits may accrue to researchers. Specialists in fishery management and specialists in international seafood trade could benefit from cooperation, a point made with respect to natural resource issues in general at a 1987 meeting cosponsored by the U.S. Department of Agriculture and Resources for the Future (Sutton ; see also Ervin and Tobey).

iii) Much more needs to be known about seafood markets. While the U.S. has a long history of research on the characteristics of domestic and foreign markets for agricultural products, seafood markets are poorly understood. Techniques used to understand markets in the agricultural sector have been used successfully in conducting research on the markets for seafood. This could profitably be expanded. There is much to know about seafood demand, pricing strategies, market structure, and supply factors.

ABSTRACT

*Cost-Benefit Analysis, like the empirical tool developed in France called Méthode des effets, tend to discount welfare changes arising from non-market or missing market phenomena. Examples in developed economies of such measurement problems, are often found in the environmental resource economics literature on non-market measurement. However, in developing economies, where transactions costs might militate against the formation of explicit markets, the household is often regarded as the principal economic unit. Thus, changes in household production and consumption, which may have no market analog in the neoclassical sense, would reflect both individual and aggregate welfare changes in terms of changing surplus conditions.*

*However, these project evaluation methods are still widely used, for example by the World Bank and the Coopération française, to quantify benefits and costs, and to identify the gainers and losers which result from a given policy, even though it is not clear that these measures capture the economic and social realities observed. In communities where subsistence and non-market activities are evident, resorting to other techniques for impact measurement is necessary.*

*The purpose of this paper is to examine the application of household production theory in conjunction with standard project evaluation technics. The development of such an approach could aid in measuring changes in non-market economic goods held within families and communities. This conceptual approach is studied within the context of Impact evaluation of a small-scale fishery project in the Tanganyika lake district of Zaire. Household-production theory applied to this case places in perspective the implicit measurement difficulties engendered by the assumption of well-functioning markets. A secondary aim of this work is to explore the dynamics of growth and change in household well-being, as a result of proposed development projects.*

## 1. INTRODUCTION

L'aide au développement, amorcée sous forme de projet, doit subir, dans la plupart des cas, une évaluation financière et socio-économique. La théorie néoclassique, construite autour des institutions de marché et d'un système de prix continu, propose à cet égard les concepts de base pour la mesure des changements en bien-être. Mais, cette mesure doit toujours être reliée, de façon directe, à un marché en décrivant une fonction d'offre, et, de demande et de façon indirecte, en établissant un prix fictif pour les marchés manquants et les non-marchés. Auquel cas, on émet les hypothèses appropriées sur : la séparabilité de la fonction d'utilité et de la fonction de production ; la continuité des contraintes de budget ; les conditions de complémentarité entre le marché et le non-marché. Cette approche théorique est largement développée dans la littérature économique qui traite de l'économie des ressources naturelles et environnementales [V. Adamovitz ; 1991] et de l'estimation des marchés parallèles ou *missing market* [(T. A. Cameron ; 1988)(E. L. Feige ; 1990)(J. Gaudin et M. Schiray ; 1984)(M. Penouil ; 1990)].

Dans la plupart des travaux appliqués, les biens non-marchands et les effets des marchés manquants sont considérés comme des phénomènes non-mesurables, du fait de raffinements conceptuels rarement utilisés. L'analyse *coût-bénéfice*, tout comme la méthode empirique développée en France sous le nom de *méthode des effets*, mesure les changements en bien-être provenant des phénomènes marchand, mais ne mentionne que de manière allusive l'existence d'activités non marchandes [(M. Bridier et S. Michaïlof ; 1990)(M. Chervel et M. Le Gall ; 1981)(J. Price Gittinger ; 1985)(L. Squire et G. Van Der Tak ; 1985)].

Malheureusement pour les praticiens comme pour les théoriciens, plus nous utilisons les hypothèses fondamentales du modèle néo-classique, notamment la prédominance du marché, moins crédibles deviennent les mesures. Et ce, malgré la littérature courante faisant état du foisonnement de marchés informels, notamment en Afrique : cet informel à la place du formel présente des problèmes de mesurage. La littérature des Droits de propriété [Coase ; 1960] nous enseigne que les coûts de transactions élevés sont responsables du type de structure des institutions autres que le marché. Ceux-ci peuvent empêcher la formulation de marchés explicites. Les innovations publiques qui doivent normalement réduire les coûts de transaction, se heurtent au problème des ressources (humaines, technologiques, etc.) limitées, et de ce fait ne peuvent assurer un rôle prédominant. Des institutions en marge de ces circuits publics et privés se développent pour assurer la distribution des ressources parmi la population. Les institutions parallèles, où les formes structurelles de famille et de communauté dominent, apparaissent comme des palliatifs à ces carences flagrantes.

En Afrique, la famille peut se concevoir comme une unité économique à part entière, voire comme la principale entité économique [P. Hugon ; 1991]. Aussi les changements dans la production et la consommation domestiques des familles, par définition non marchandes, traduiront-ils les modifications de bien-être au niveau de la structure familiale en terme de changements des conditions de surplus. Cela signifie que les fondements théoriques issus de la mesure du bien-être doivent être capables de traiter de manière cohérente la famille dans un contexte de coûts de transactions très élevés.

Il convient donc de compléter les analyses basées sur la "New Institutional Economics" par les extensions théoriques qui expliquent le comportement des populations concernées. Pour ce faire, la Théorie de Production des Ménages (TPM), comme support théorique, peut se révéler pertinente pour l'appréciation des changements en bien-être. Les modèles de production domestique développés dans les PVD au début des années 80 se sont attachés à examiner les activités agricoles avec en toile de fond les phénomènes d'autoconsommation [(L. Squire et al. ; 1986)(A. De Janvry et al. ; 1990)]. Et cela, bien que la production domestique ait intéressé dès les années 30 les économistes comme S. Kuznets, L. Esptein et d'autres. Néanmoins, trente années s'écouleront avant que celle-ci n'acquière ses premières lettres de noblesse sous l'impulsion des Gary S. Becker, Lancaster... La *nouvelle théorie du consommateur* a mis en évidence un processus de production domestique : à l'activité de consommation des ménages se substitue une activité de production des satisfactions [J. P. Faugère ; 1980]. Cette nouvelle approche combinée aux travaux de T. P. Schultz et R. Pollack sur l'allocation du temps des individus a permis d'appréhender le problème de la mesure de la production domestique dans une optique plus élargie.

Le premier objectif de cette communication est d'utiliser les différentes approches de la théorie économique pour développer des fondements théoriques en vue de mesurer les changements de bien-être dans un contexte de coûts de transaction élevés où la famille joue un rôle dominant.

Nous essayerons ensuite d'explorer les questions relatives à la perception du bénéfice entre les receveurs et les donateurs, et les difficultés de mesurage qu'implique une injection de dollars ou de francs dans un tel contexte. En étudiant, notamment, l'efficience inter-temporelle des projets face à la stabilité du panier de consommation de la famille, même

s'il apparait comme évident que celui-ci change durant la période étudiée [(M. Bridier et S. Michaïof ; 1990)(M. Chervel et M. Le Gall ; 1981)]. Si, à la fin du projet, les infrastructures économiques existantes ne peuvent supporter les nouvelles habitudes de consommation de la population affectée, les impacts à long terme d'une telle initiative de développement se manifesteront par une dépréciation accrue de l'économie.

De plus, les conclusions des analyses de projet se révèlent incomplètes : elles focalisent leur attention sur les seuls aspects financiers et économiques et ne traduisent qu'une relation unilatérale projet-population concernée, sans mentionner la relation inverse population concernée-projet. Le comportement des individus va en effet affecter la vie du projet et donc influencer les résultats financiers escomptés.

Un survol de la littérature touchant les aspects d'évaluation de projet, de production non marchande, de production domestique et de comportement humain révèle une connaissance approfondie dans chacune de ces approches où psychologie et économie s'enrichissent de leur apports respectifs. Une recension a révélé l'absence d'une synthèse des savoirs propres à chaque spécialité pour mesurer les changements en bien-être des populations affectées par un projet. Il va donc sans dire qu'une étude approfondie dans ce domaine, étude qui peut au premier abord sembler marginale, devrait toutefois permettre de combler une lacune et d'améliorer par conséquent les outils de prise de décision pour la mise en place de projets ou de politiques de développement (en particulier dans les PVD).

Le cadre de référence de cet article est l'Afrique, et plus particulièrement la région du lac Tanganyika (Est du Zaïre) où le premier auteur a séjourné pendant l'été 1991 pour recueillir les données nécessaires à la réalisation de l'étude de faisabilité financière et socio-économique d'un projet de pêche artisanale [P. Failler ; 1991]. L'Afrique, de par la complexité de ses structures familiales, communautaires et sociétaires en général, projette une image ambiguë où la rationalité néoclassique perd pied rapidement. Il sied donc d'appréhender ces différentes structures pour comprendre la façon dont elles interfèrent avec la mise en place et la vie d'un projet.

La démarche suivie tout au long de cette communication consistera donc à développer une esquisse théorique sur la famille étendue en Afrique dans l'optique néo-institutionaliste avec comme support la TPM, et ce, dans un effort pour formuler des conclusions concernant la validité des mesures du surplus dans ce contexte d'évaluation de faisabilité de projets. L'approche néo-institutionaliste consiste à tirer ses concepts théoriques des observations faites sur le terrain. Nous commencerons donc par une description de la structure économique et sociale des communautés africaines. La deuxième partie viendra renforcer cette description par une explication théorique des concepts de famille et de communautés villageoise et ethnique, en regard des relations et des contrats qui régissent les comportement des individus entre eux. La troisième partie reprendra, dans un premier temps, les formulations de la firme chez Coase et la notion d'altruisme définie par Becker pour, dans un second temps, tenter d'appuyer sur des fondements théoriques notre perception de la mesure du surplus dans de telles entités économiques.

## 2. DESCRIPTION DES INSTITUTIONS ÉCONOMIQUES DES VILLAGES DE PÊCHE AU BORD DU TANGANYIKA

Le projet de pêche artisanale commandité par le Comité Catholique contre la Faim et pour le Développement (CCFD, Paris) avait pour objectif de former un Groupement d'Intérêt Économique (GIE), où les pêcheurs seraient partie prenante [P. Failler et M. Kamitenga ; 1991]. Ces pêcheurs partagent leur temps entre une pêche de subsistance et une agriculture de même nature. L'agriculture, dans la région bordant le lac Tanganyika, pour 94 % des pêcheurs interrogés par la FAO, constitue une importante source de revenu et seulement 3 % d'entre eux dépendent entièrement de la pêche [K. Leenderste et B. Horemans ; 1991].

Trois localités zaïroises avaient été sélectionnées en raison de leur proximité des meilleurs lieux de pêche et de l'accessibilité de leurs berges : Baraka, Kazimia et Dine. Les observations suivantes ont été recueillies d'après des constatations de visu appuyées par une maigre littérature, produite localement sous forme de rapports d'activité pour le Gouvernement zaïrois. Ces trois localités qui s'apparentent davantage, de par leur population importante, à des villes qu'à des villages présentent cependant les mêmes caractéristiques d'infrastructure que ces derniers. Aucun de ces lieux n'est alimenté en électricité, et seuls Baraka et Kazimia possèdent l'eau courante. Les communications se caractérisent par : un réseau routier difficilement praticable en saison sèche (il faut six heures pour parcourir les quatre-vingt-dix kilomètres séparant Uvira de Baraka) et inutilisable pendant la saison des pluies ; un transport maritime important mais très dangereux en raison de normes de sécurité inexistantes. Un tel système occasionne des coûts très élevés de transport pour les marchandises et les déplacements humains.

Les coûts de transport associés aux profits réalisés par les nombreux intermédiaires peuvent multiplier le prix d'un sac de poisson séché (45 kg) par quatre sur une distance de deux cents kilomètres. En règle générale, on peut mentionner que plus l'on s'éloigne du lieu de production et l'on s'enfonce dans les terres, plus les coûts unitaires par kilomètre parcouru augmentent. Ceci rend très difficile le commerce sur de longues distances et explique, entre autres, l'absence de diffusion de certains produits dans des villages de taille réduite qui ne sont pas situés près des routes principales ou sur le trajet fluvial. Les coûts de transactions ne permettent donc pas à tout un chacun de disposer à sa guise d'un éventail de biens. Le recours à la production domestique s'avère de ce fait une nécessité à laquelle les populations ne peuvent se soustraire.

Un système de phonie qui palie médiocrement l'absence de téléphone assure une liaison minimale entre les autorités des différentes localités de la région. L'absence d'électricité interdit toute information télévisée et limite l'information retransmise par radio. La diffusion de la presse est inexistante : les journaux sont imprimés à Kinshasa (Capitale), située à quelque deux mille kilomètres du Tanganyika. Il est donc clair que, même si le Burundi diffuse sa presse et ses émissions de télévision dans la ville d'Uvira (proche de la frontière), dès que l'on descend vers le sud la propagation de toutes ces informations s'interrompt. Le système d'information dans sa généralité présente donc des déficiences handicapantes pour une région si riche en ressources naturelles [stock halieutique important ; essences précieuses (Teck, ébène, acajou) ; or, diamants et minerais convoités].

La localité de Baraka représente un centre économique dû au simple fait que le transport fluvial alimente deux fois par semaine son marché, principalement en produits de consommation courante comme le poisson, le manioc, l'essence, les médicaments et la bière. Tous les producteurs de poissons séchés et frais viennent de Dime, de Kazimia (au sud) vendre leur poisson aux grossistes venus du nord du lac. Le marché se définit comme le lieu de rencontre des producteurs, des commerçants et des particuliers. Les prix sont, pour le poisson par exemple, fixés en fonction de la qualité, du rapport entre l'offre et la demande, et de l'éloignement par rapport au lieu de production. Les fluctuations sont très fortes dans un intervalle mensuel. L'instabilité des volumes de capture est amplifiée par les mécanismes de marché en vigueur.

Une chute de la production provoque un goulot d'étranglement à l'accès des produits : le nombre de grossistes en présence devient faible, car peu d'entre eux ont les moyens de se fournir à des prix très élevés. Le nombre d'intervenants sur le marché de gros comme de détail étant réduit, le jeu de la libre concurrence ne s'établit pas correctement car le besoin de la population est toujours le même mais avec une disponibilité réduite.

Cette localité qui abrite environ 30.000 personnes (les recensements datent et sont très imprécis) a connu son ère de prospérité sous la colonisation belge, alors qu'il existait des usines de transformation du coton. Il y avait à cette époque, avant l'indépendance du Zaïre en 1960, un réseau routier entretenu, de l'électricité, des stations d'essence, etc.. Aujourd'hui, il ne reste qu'un hôpital, une mission catholique, des écoles de niveau primaire et quelques magasins peu achalandés. Seul le marché bi-hebdomadaire assure à Baraka une dynamique économique qui suffit à lui maintenir un rôle manifeste au niveau régional. La pêche n'est cependant plus qu'une activité de subsistance dans la majorité des cas. Un recensement des unités de pêche zaïroises effectué par la FAO en mai 1991 a révélé une forte diminution de la pêche artisanale au détriment de la pêche coutumière entre 1984 et 1991 (respectivement : -48 % et +32 %).

La localité de Dime présente des conditions plus précaires que Baraka. Elle rassemble une vaste communauté de pêcheurs actifs tout au long de l'année. Les conditions de vie sont véritablement précaires : pas de dispensaire, d'hôpital, de route, etc.. L'unique vocation de ce village réside dans l'activité de pêche artisanale et coutumière. Kasimia offre des conditions moins hostiles mais, hormis une coopérative de pêcheurs et d'agriculteurs, aucune activité industrielle n'est recensée. Elle possède cependant des dispensaires et des écoles. La population d'environ 10.000 habitants en 1988 se concentre autour de l'activité de pêche artisanale.

Quatre ethnies composent la population des nombreux villages qui jalonnent les rives du lac et les localités visées par le projet : les Babembe, les Bavira, les Barundi et les Bachi. La coexistence de plusieurs ethnies dans un même village est courante. On peut cependant mentionner que les Babembe et les Bavira sont les plus nombreux et les plus anciennement implantés. Les Barundi et les Bachi ont commencé à fuir le régime ségrégationniste du Burundi depuis 1971 et se sont installés massivement sur la rive zaïroise [M. Maes et al. ; 1991], non sans heurts avec les communautés des Babembe et des Bavira. Ces derniers vont même jusqu'à constituer 80 % de la population de certains villages. L'appartenance à une communauté est ressentie très fortement par les individus qui, avant toute chose s'y identifient. A l'intérieur de chaque communauté il existe un système de droit qui régit les actions de ses membres. A titre d'exemple, on a pu assister àl'arrestation et au jugement d'un militaire en fonction par les représentants de la communauté des Bavira parce que celui-ci avait volé un cochon à un membre de la même appartenance ethnique que lui ! Le rôle attribué généralement à la police est ainsi substitué par un code de conduite et de répression communautaire qui veille au respect de certaines règles.

On peut s'imaginer à partir de cet exemple l'ampleur du processus communautaire. Il réglemente la vie de ses membres en ne tenant que peu compte du système juridique mis en place par l'état et appliqué par la police locale.

Le système judiciaire, policier, militaire, toute comme l'ensemble des institutions publiques, opèrent une ponction importante sur l'ensemble du système économique, que ce soit au niveau de la circulation des biens marchands entre les différentes zones (délimitation politique des régions) ou au niveau des marchés directement. Au vu de leur salaire, le phénomène de corruption peut trouver une explication : un employé de bureau gagne un dixième du revenu qu'il lui faudrait pour nourrir sa famille ; il faut donc qu'il se procure les neuf dixièmes quelque part ! Le fonctionnaire assimile son travail à un travail de gestionnaire ; il faut en effet qu'il gère au mieux son périmètre de juridiction qui dépend directement de sa fonction et de son grade. Les droits de passage et autres prélèvements se concrétisent par une augmentation sensible des coûts de transaction, ce qui ne fait qu'accentuer la pression sur les familles qui recourent au marché. Les impôts ne représentent qu'une part de plus en plus faible du revenu car ils ne sont pas indexés sur l'inflation depuis 1989 (inflation galopante de 50 %, par exemple, pour le mois de juillet 1991).

La famille, face à de tels coûts, est repliée sur elle-même dans le but de produire les biens qui lui sont indispensables. Le type de famille rencontré dans les localités du projet peut se schématiser ainsi : un tronc composé du pêcheur, de son épouse ou de ses épouses dans les cas de polygamie, de ses enfants, et de branches composées de vieillards, d'inactifs, des proches parents, de leurs enfants, etc.. Ces familles de vingt individus et plus vivent dans un espace très restreint, souvent sous le même toit.

Un recensement effectué dans le cadre du projet de pêche artisanale auprès des pêcheurs a permis de mettre en lumière la nature des revenus, la ventilation des dépenses, et l'identification des personnes qui génèrent un revenu au sein de telles familles élargies. On a pu constater ainsi que le revenu principal provient de l'activité de pêche du chef de famille et que l'activité principale de sa ou de ses femmes est l'agriculture. Les principales dépenses peuvent globalement se ventiler comme suit : achat de biens alimentaires pour 75 % du revenu, acquisition de vêtements pour 15 % et santé pour les derniers 10 % [P. Failler ; 1991].

A partir de cette description sommaire des fonctions des villages, de la place de la famille et de la communauté, il est intéressant d'analyser la nature des relations qui régissent ces deux institutions, maîtresses du paysage social zaïrois et africain.

## 3. OBSERVATIONS PLUS APPROFONDIES DE LA FAMILLE ET DE LA COMMUNAUTÉ

### *3.1 La famille élargie*

Comme il a été souligné ci-haut, le concept de famille ne revêt pas la même signification en Occident qu'en Afrique. En Europe la famille peut se définir comme une cellule nucléaire relativement hermétique, presque exclusivement constituée des deux parents et de leurs enfants. L'Afrique fait éclater ce concept de famille mononucléaire pour apparaître sous une forme plus élargie, où un ensemble de personnes cohabitent sans avoir des liens filiaux ou une parenté directe.

Dans ce contexte de famille élargie, les centres de décisions correspondent rarement aux centres de procréation et peuvent en outre différer des centres de prise en charge [P. Hugon ; 1991]. Les familles sont regroupées autour d'un chef de famille ou de quelques personnes qui garantissent, par leur travail marchand, un revenu monétaire permanent. On peut donc scinder la famille en deux fractions distinctes : le noyau et la périphérie. Le noyau apporte un revenu monétaire qui lui permet d'assumer la prise en charge de la famille périphérique, ce qui lui confère une certaine autorité sur le reste de la famille. En contrepartie, la périphérie consacre le plus clair de son temps à rendre des services divers au noyau et à l'ensemble de la famille. Ces services ou activités assumés par la périphérie sont chronophages. Ils consistent à élever et éduquer les enfants (oncle, grand frère), àassurer le ramassage du bois, les activités de cueillette, etc. On peut, dans ces conditions, attribuer une valeur fictive aux activités assurées par la périphérie, exprimable en termes de temps. Un taux de salaire fictif pourrait être attribué en référence au taux de salaire marchand.

La famille africaine se doit de comporter plusieurs enfants. C'est à la fois un signe de richesse et de bonne santé mais les enfants représentent aussi un capital humain important qu'il convient de faire fructifier. Les enfants sont en effet une

source non négligeable de main d'oeuvre non marchande, disponible au sein de la famille. Mais ils constituent également une forme d'assurance-retraite : les parents seront pris en charge par leurs enfants lors de leur cessation d'activité. On peut rapprocher le comportement des parents avec celui du propriétaire d'un portefeuille de titres négociables. Cet investissement, comme dans un portefeuille d'action, rapporte quelque bénéfice qui, dans notre cas, peut se concevoir comme de la main-d'oeuvre non marchande et un régime d'assurance retraite. Cela suggère que la structure familiale peut être étudiée dans un contexte de *risk management*. Becker (1981) souligne par ailleurs que, dans les familles modernes occidentales, l'investissement en capital humain et non-humain des parents pour leurs enfants se traduit simplement en terme de satisfaction, en fonction entre autres de la qualité des enfants.

### *3.2 La communauté villageoise*

La communauté villageoise gère la vie sociale et économique de l'ensemble des familles appartenant au même groupe ethnique. Cette structure se caractérise par des règles assimilables àun code de conduite communautaire qui apparaît sous les formes suivantes :

- Les individus doivent consacrer une partie de leur temps journalier aux activités communautaires. Ce temps communautaire est voué à la gestion des affaires courantes de la tribu ou du groupe ethnique.
- Un système de donations-obligations régit les relations des individus ou des représentants familiaux avec le reste de la communauté.

Le temps communautaire est pris non seulement sur les temps de loisir mais aussi de travail. Certaines dates, certaines manifestations météorologiques et d'autres événements obligent les individus à ne se consacrer qu'aux seules activités et palabres communautaires [F. R. Mahieu ; 1989]. Le temps communautaire est donc fonction des temps de travail marchand, de travail domestique et de loisir.

Le système de donations-obligations constitue un garde-fou pour l'ensemble de la communauté villageoise ou ethnique. Il assure en effet un rôle de redistribution des ressources des plus nantis vers les plus dépourvus. Cette fonction sociale permet le maintien d'une certaine homogénéité parmi le groupe communautaire. En contrepartie, les individus à la solde de la communauté et donc redevables de sa bienveillance se doivent de fournir du temps pour vaquer aux nombreuses taches communautaires. Les familles doivent s'acquitter de leurs obligations pour être en observance avec la communauté et ne doivent surtout pas y déroger sous peine de s'en voir exclues. Les obligations, en plus du caractère d'entraide incessant, possèdent un caractère ponctuel, notamment, lors des décès, des fêtes, des achats onéreux de certaines familles de la communauté. Les donations, constituées principalement de dons alimentaires, vestimentaires et quelquefois monétaires, sont perçues par les individus les plus défavorisés financièrement.

Les obligations et les donations sont fonction du revenu de la famille, en considérant que les obligations lui sont proportionnelles et les donations inversement proportionnelles.

On peut arguer que ce système communautaire concourt, à l'instar de la famille élargie, à la dissipation de la rente. Les individus qui gagnent les meilleurs salaires se voient affligés d'une famille très nombreuse, proportionnelle à leurs salaires, et de plus, se voient contraints par le système d'obligation de céder une partie de leur revenu à la communauté, sous quelque forme que ce soit, pour entretenir la solidarité. Les individus ayant un revenu monétaire suffisant s'acquittent de leurs obligations en terme de biens incluant des inputs monétaires plus ou moins importants ; les individus défavorisés quant à eux, sont obligés de consacrer leur temps pour se libérer de leurs obligations.

Le temps peut donc s'échanger contre des biens produits par la famille, voire de l'argent dans certaines occasions. On peut sur ce simple fait présager des modifications de la nature des obligations des individus impliqués par un projet de pêche.

Les concepts de famille élargie, de communauté ont permis de dresser un panorama qui ne se veut pas exhaustif, mais qui présente les caractéristiques principales de la société africaine observée. Un des points importants concerne justement la relation entre la famille étendue, la mesure du bien-être et la dissipation du surplus. Cette relation est traitée de façon théorique dans la section qui suit.

## 4. UNE CONCEPTION BECKER/COASE DE LA FAMILLE AFRICAINE

La description précédente du contexte institutionnel de la famille africaine nous a permis de voir clairement la "nature de la famille" dans son contexte. Rappelons-nous maintenant le fameux article de Coase en 1937 intitulé "The nature of

the firm" : de nombreux parallèles semblent surgir entre ces deux institutions. Il est raisonnable d'affirmer que les coûts de transactions limitent le développement du marché dans un tel contexte. L'impact d'un tel développement est double car une part relativement importante des biens de consommation n'est pas achetée mais produite par la famille, ce qui en retour, sur une plus large échelle, limite des occasions d'emploi hors de la famille.

Dans une situation extrême où les coûts de transactions sont très élevés, le commerce entre familles est faible, voire inexistant. Tout le monde se trouve dans une situation de vie précaire proche de l'autarcie. Dans de telles économies de subsistance, la famille peut être assimilée à la firme au sens de Coase, et vice-versa.

Dans l'analyse de la firme par Coase, la première motivation pour créer une telle entité est de réaliser des profits. En formant une organisation, avec une autorité centrale (entrepreneur), la famille se dispense de certains coûts de transactions en évitant le recours au marché [R. C. Coase ; 1937]. Cheung (1983) propose d'autres raisons pour l'émergence d'une firme : division du travail, diminution du risque et coordination des activités de production. De par les hypothèses implicites du modèle néoclassique (information parfaite et absence de coûts de transaction [T. Eggertsson ; 1991]), il ne semble pas évident de justifier l'existence des firmes qui ont pour raison d'être la maximisation des profits, en exploitant l'information imparfaite à la fois à l'intérieur de la firme, et à l'extérieur de la firme au niveau du marché. C'est dans ce contexte d'information imparfaite que le phénomène de quasi-rente existe. Avec un nombre de marchés suffisant, le surplus peut être appréhendé en termes monétaires. Et parce que l'entrepreneur cherche à maximiser sa quasi-rente, celle-ci devient une mesure pertinente du bien-être.

La Nouvelle Économie Institutionnelle, basée sur les travaux de Coase (1937), Alchian (1950) et Cheung (1983) s'intéresse principalement à la logique des arrangements contractuels, entre autres à la question : pourquoi une forme contractuelle domine-t-elle l'autre [T. Eggertsson ; 1991] ? La firme peut se concevoir comme un lieu de connexion des contrats, en fonction de la compétence de l'entrepreneur et des coûts de transaction environnementaux. Cette définition, admise pour les firmes classiques, est aussi vraie pour les autres entités de production organisée. Nous pensons, àcet égard, qu'il est justifié de regarder l'unité familiale du contexte africain comme une forme particulière de firme.

Pourquoi un pont doit-il être construit entre les travaux de Coase sur la firme et ceux de de Becker sur l'altruisme ? Dans une firme typique, comme nous l'avons décrite, l'entrepreneur met en suspens quelques aspects du marché, parce qu'il dirige lui même l'allocation des ressources àl'intérieur de la firme avec des formes de contrats particuliers. Les facteurs de production sont ainsi ordonnés de façon à obtenir une quasi-rente ou une rente, en fonction de la structure de temps. Dans un environnement où les coûts de transaction sont manifestes, les arrangements contractuels ne demandent pas une rigidité aussi soutenue que le marché l'exige pour produire une quasi-rente. Mais l'ensemble de toutes les composantes de la fonction de production doit être déterminé pour placer cette production à un niveau supérieur au coût variable moyen. Dans une firme altruiste, le profit ne constitue pas la forme première de motivation des individus, il est substitué par le maintien des contrats entre les différents facteurs de production. Le raisonnement doit être en fait le même que celui qui est décrit par Becker, mais augmenté de la connaissance suivante : la faible opportunité d'emploi oblige les personnes qui ont un travail à le conserver. Les familles altruistes selon Becker (1981) possèdent plus d'assurance que les autres car elles assurent leurs membres contre les aléas et les vicissitudes de la vie.

Nous pouvons définir une firme altruiste comme une entreprise multi-extrants avec au moins un extrant destiné au marché $m_j$ (j = 1 - k), et un extrant non destiné au marché $Z_i$ (i = 1 - n). Tous les outputs sont produits par une combinaison du temps T et d'argent M. Dans le cas où la firme vend du temps à un taux de salaire w, on peut écrire les deux principales contraintes comme suit :

$$T = T_w + T_n$$

$$M = g(w, T_w)$$

Où $T_n$ est le temps de travail non rémunéré de la firme, $T_w$ le temps de travail rémunéré et w le taux de salaire. La firme va en général vendre plus d'unités de temps rémunéré si w augmente, bien que les coûts d'opportunité de telles ventes croissent. La simplification exprimée dans la formulation $T_w = m_j$ ne met pas en défaut la généralité de l'analyse, $T_w$ étant le seul extrant destiné au marché.

Le facteur $T_n$ est ainsi dirigé dans son activité par le fournisseur de M. En utilisant le cadre théorique de Lancaster/Becker, les $Z_i$ - élaborés par les combinaisons de $T_n$ et M - sont des produits non marchands consommés à l'intérieur de la famille. Par contre, dans un contexte de firme classique ou, dans d'autres regroupements de production, les $Z_i$ sont des extrants marchands, résultats des contrats internes entre le gestionnaire et les facteurs de production. Dans notre cas, les $Z_i$ sont produits de manière interne sous des conditions standard que l'on retrouve dans la théorie Consommateur/Producteur traitant des biens non-marchands : ce qui leur confère des prix fictifs bien définis.

Il semble que dans les nations en développement le népotisme définisse la firme classique et que la subsistance définisse la famille-firme. Les coûts associés aux contrats implicites et forcés au sein de la famille, même avec une parenté éloignée, associés avec l'obligation sociale de redistribution au sein de la famille (altruisme) conduisent à une organisation familiale très large par rapport à que l'on rencontre dans les nations développées.

Nous pouvons introduire, pour objet de présentation, une fonction d'utilité des biens non-marchands $Z_1$ et $Z_2$, pour un niveau minimum acceptable, nécessaire au maintien en vie des individus en question : {Min $Z_1$ ; Min $Z_2$ }. Pour l'intégrité et le réalisme de notre analyse, nous considérons que c'est une "decision-making unit" qui détermine le minimum acceptable standard de consommation, par exemple, de produits alimentaires et d'habillement (ces standards peuvent toutefois différer selon les familles). Considérant un espace où la fonction de production est continue pour les $Z_i$, on peut définir une frontière des possibilités de production. Aux fins d'illustration, supposons que $Z_1$ a nécessité dans sa composition plus d'argent que $Z_2$. L'équilibre initial A (*cf.* figure) suggère que tous les acteurs ont juste de quoi se maintenir dans la firme. La quasi-rente est donc réduite à rien. Supposons maintenant que le taux de salaire horaire $T_w$ subit une augmentation imposée des facteurs externes. Selon les hypothèses énoncées, ceci entraînera un déplacement vers l'extérieur de la frontière de production initiale (nouvelle frontière similaire à celle décrite plus haut). La production de $Z_1$, à forte intensité de capital, augmentera davantage que la production de $Z_2$ qui nécessite plus de travail.

Dans une firme, chaque barrière à la transaction représente des coûts réels ; la taille de la firme dépendra de ces coûts de transaction en fonction de la compétence de l'entrepreneur à commander et à régir ses facteurs de production. La distance de A à B, mesurant les changements en surplus de la famille, de la firme et donc de la société, suivant les hypothèses émises, se traduira à coup sûr en termes monétaires. Lorsque les familles constituent des unités économiques de la sorte, avec des coûts de transaction environnementaux, les changements à l'équilibre dans les taux de salaire ou dans les prix des biens marchands se reflètent sur le surplus, en termes d'externalités physiques ou de variation du revenu monétaire.

Cependant, compte tenu de la réalité du contexte africain, les augmentations exogènes de revenu peuvent étendre le périmètre de la famille par un déplacement vers l'extérieur de la courbe de frontière des possibilités de production, celle-ci caractérisant des changements dans les besoins minimums en $Z_i$ requis pour le fonctionnement de la firme-famille. Les prises de décisions humaines de cette firme vont se manifester au niveau des contrats internes, notamment par une modification de $T_n$ , dans le but de garantir la viabilité de l'unité économique. Les contrats portant sur $T_n$ sont conclus lorsque (min $Z_1$ ; min $Z_2$) est tangente à la courbe des possibilités de production, au point C. La firme s'agrandit et la production d'output doit augmenter.

La quasi-rente a donc disparu au sens monétaire du terme, mais se trouve présente sous forme déguisée dans le capital humain et les qualités que l'on peut lui attribuer.

Ainsi se pose un problème pour les praticiens qui cherchent le moyen par lequel appréhender les changements de surplus. La dissipation de la rente n'implique pas une absence de manifestation concrète, ni des changements non bénéfiques pour les populations concernées. Les biens non marchands peuvent être évalués d'après les conditions décrites *supra*, mais une fois la rente fixée dans sa forme de capital humain, il semble absurde d'insister avec des mesures monétaires du bien-être, spécialement lorsque la structure institutionnelle de la firme ne se manifeste pas par la formation d'un surplus, mais plutôt par la recherche, la capture et la dissipation de la rente dans le but de maintenir le capital humain. Dans ces cas, il semble que les mesurages directs des changements dans les biens et l'amélioration de la qualité de la vie seront plus appropriés que les mesures monétaires. Cela suggère, pour le mesurage de la santé des organismes, d'opter pour des approches de type systèmes écologiques, en complément d'une révision des notions de bénéfice économique et enfin, d'une définition de ce qui doit être réellement pris en compte.

## 5. CONCLUSION

La complexité des structures institutionnelles africaines oblige une révision des concepts développés par les économistes néoclassiques. Ces concepts, adaptés au système économique des pays développés rencontrent bon nombre de difficultés lorsqu'il s'agit de les transposer en Afrique. Un examen approfondi et une remise en question des méthodes de mesure de surplus, de bien-être en général permettra de pallier les inepties actuelles des évaluations de projet. La panoplie d'outils àla disposition des praticiens devra entre autres inclure les approches néo-institutionnelles et les approches de l'économie des systèmes écologiques.

Dans le cas des projets de pêche, la substitution en terme de temps des activités jadis pratiquées par la seule activité de pêche ne provoque pas toujours l'effet escompté dans les analyses de projet. Celles-ci supposent en effet qu'une augmentation du revenu se traduira par un recours plus important au marché, par des dépenses plus élevées pour des produits de consommation durables. Mais c'est oublier le coût d'opportunité associé au renoncement de l'activité secondaire agricole : la famille du pêcheur ne peut pas se passer de la culture de son lopin de terre. Le recours àd'autres personnes sous contrat monétaire n'étant pas envisageable, l'incorporation au sein de la famille de nouveaux membres demeure la solution envisageable : le déplacement du point B au point C peut, notamment, s'expliquer par ce fait.

Une augmentation des revenus des pêcheurs se traduira par un agrandissement de la taille de la communauté au même titre que la famille. Il semble cependant présomptueux de vouloir décrire *a priori* des changements dans les obligations et les donations. Cependant, selon la logique communautaire, le système d'équité sociale permettra aux individus et aux familles qui ne bénéficient pas directement du projet d'en percevoir les effets bénéfiques sous la forme de donations. Mais là aussi, la mesure monétaire rencontre les mêmes difficultés que pour l'unité familiale, les échanges communautaires revêtant, rappelons-le, les formes de temps, de biens divers produits de façon domestique et, dans certains cas, monétaires.

Les populations de pêcheurs ont développé au fil des projets des comportements que l'on pourrait qualifier d'opportunistes. Un projet de pêche signifie très clairement un apport de capitaux, de matériel, de savoir-faire étranger... Il n'est aujourd'hui plus perçu de la même façon qu'il y a vingt ans. Le pêcheur sait que, même si le projet dans lequel il est inscrit ne fonctionne que quelque années, il en tirera un bénéfice substantiel et ponctuel, soit sous forme monétaire (revenus), soit sous forme de matériel de pêche. Le pêcheur perçoit clairement qu'il a tout intérêt à se manifester dans le plus grand nombre possible de projets car, quoiqu'il advienne, il se considère gagnant, n'ayant investi que son temps. Il peut être assimilé à un chasseur de rente qui cherche à maximiser ses gains sur un espace de temps le plus restreint possible. Le phénomène de *rent-seeking* peut se définir, selon Eggertsson, comme la tentative, pour les individus, d'augmenter leur richesse personnelle, tout en contribuant en même temps, mais de façon négative à la création de la richesse nette de leur communauté. Cette définition, au vu de la réalité du contexte africain, doit être reconsidérée, car dans le cas d'un apport monétaire extérieur, la communauté étudiée représente un ensemble de familles, impliquées de près ou de loin dans le projet, auquel cas le phénomène de *rent-seeking* peut se concevoir comme une augmentation de la richesse des familles de pêcheurs et de leur communauté au détriment de l'organisme responsable, et, dans une plus large mesure, de la communauté occidentale.

A cet égard, on pourrait appliquer les analyses de comportements des individus face au risque pour raffiner l'analyse des changements dans les préférences. . Un projet peut être appréhendé en terme de gain ou de perte : la perception d'un projet peut donc s'analyser à la lumière de la théorie des jeux. Il apparaît que les pêcheurs ont pour objectif de maximiser leurs gains en saisissant toutes les occasions offertes. D'autres travaux, comme ceux de M. Willinger, montrent l'aversion des agents vis-à-vis de l'ambiguïté, et ce dans une fonction d'Utilité Espérée. Les travaux de D. Bromley soulignent - en économie de l'environnement - l'aversion des agents envers une incertitude en termes de gain mais un comportement de *risk-lover* vis-à-vis d'une incertitude en termes de perte.

Une application de ces théories permettra sans aucun doute de mieux expliquer la dynamique des changements de comportement des agents en regard d'un projet.

Pour éviter la dissipation de la rente, de nombreux projets de pêche ou de développement en général mettent en place un système d'épargne forcée. Cette épargne est prélevée sur le salaire des pêcheurs (cas du projet de pêche sur le lac Tanganyika). Mais on peut se demander si les efforts pour arrêter la dissipation de la rente sont bien réfléchis, et si oui pourquoi ? Tant que le problème de la société sera la minimisation du nombre d'individus qui tombent au dessous de Min $Z_i$, il semble que les problèmes de la dissipation de la rente ne soient pas pertinents.

Enfin, selon Gary S. Becker, la substitution d'un emploi rémunéré à un emploi domestique provoque une augmentation du coût "d'élevage" des enfants à cause d'une augmentation des coûts associés à une heure de travail (coûts d'opportunité). Dans le cas d'un projet de pêche, la substitution de l'activité de pêche de subsistance par une activité artisanale voire plus industrielle engendre le même type d'effets que ceux mentionnés par Becker. Pour la famille, cela se manifestera par une augmentation des coûts associés au maintien de la famille élargie. Comment considérer ces effets induits ? Un pas vers le progrès ou un frein au développement harmonieux d'une société dans son environnement institutionnel, culturel et écologique. Question posée avec beaucoup d'acuité par un monde occidental qui s'aperçoit d'une dichotomie grandissante entre ses institutions et leurs mécanismes et son environnement écologique. Le débat est ouvert...

# Commercial Fisheries and Sport Fishing: Conflict and Cooperation

**Tsunenori Kusakawa**

Faculty of Marine Science and Technology, Tokai University, 3-20-1 Orido, Shimizu, Shizuoka, 424 Japan

ABSTRACT

*Conflicts between commercial fisheries and sport fishing are now becoming a serious problem, because they take the same renewable resources, especially in coastal waters of developed countries.*

*In Japan, the popularization of sport fishing with the improvement of incomes, the reduction in working hours and the advancement of resources-management-type fisheries based on the propagation of fisheries resources and etc., have caused complicated problems between them.*

*Sport fishing, however, makes a contribution to the economic vitalization of fisheries communities with commercial fishermen acting as guides for sport fishermen, running guest-houses, etc.*

*Such competition and cooperation imply not only underlying issues between commercial fisheries and sport fishing, but also more basic issues such as how to coordinate the fisheries use and other uses of waters, or how to position fisheries management into coastal zone management.*

*The present status and the regimes of commercial fisheries and sport fishing in Japan, and the recent development of coordination schemes are firstly reviewed in this paper. Then coordination mechanisms under the initiatives of the parties concerned are analyzed through case studies. Finally rational relationships between coastal zone management and fisheries management in such new situations are considered.*

## 1. PRESENT STATUS OF COASTAL FISHERIES AND SPORT FISHING

Japan is one of world leading fishing nations and the industrial fisheries for offshore and far sea are very common in the world. In 1989, 71 % of the marine fisheries production in volume came from offshore and far sea fisheries, as shown in Table 1.

In terms of value, however, coastal fisheries, defined as operations conducted in local waters with boat less than 10 tons or without boat, accounted for 53.6 % of the total harvest of 2,520.8 billion yen, including aquaculture in the same year, as shown in Table 2. This is mainly due that coastal fisheries harvest high-value species at the form of fresh or live.

The importance of coastal fisheries is more evident in terms of No. of commercial fishermen. As shown in Table 3, coastal fishermen accounted for 80.4 % of the total 382.7 thousand commercial fishermen in 1989.

Japanese fisheries is faced with the difficult problems. Table 1 also shows the decreasing catch of far sea fisheries and the stagnant harvest of offshore and coastal fisheries. Japanese demand for fishery products is firmly-rooted and about 42 % of the animal protein intake came from fishery products in 1988.(Food Supply and Demand) The gap between the dull domestic production and the increasing demand is covered by the import. The import dependent ratio (import/domestic demand) for edible fishery products increased to 30 % in 1988 from 10 % in 1975. (Food Supply and Demand)

Table 2 also shows the decrease of the production value due to the competition with other substitute foods and import. Table 4 shows the relative decline of the income of fishery household compared with other households and the declining ratio of income from fishery in the total income of fishery household. In such conditions, No. of commercial fishermen shows the decrease and the age composition are becoming older due to the declining recruitment of young aged as shown in Table 3. In short, fisheries in Japan are losing its attraction.

To cope with these problems, central and local governments, and fishermen theirselves under the initiative of FCAs (fishermen's cooperative association), intend to revitalize coastal fisheries through the propagation of resources, the improvement of fishing grounds, the introduction of marine recreations into fishery business and so on.

On the other hand, water dependent recreations are becoming popular through the improvement of incomes and the reduction in working hours. Sport fishing is typical water dependent recreations in Japan and the total man-days of sport fishing accounted for 35 million in sea and over 11 million in inland in 1988, and is expected the more future growth. Table 5 shows the man-days of marine sport fishing by category. Total man-days of marine sport fishing increased 56 % during ten years. As shown in this Table, angling took 80 % and next came shellfish gathering.

Table 6 shows the total man-days of marine sport anglers by use of guide and boat. In 1988, 19.2 % enjoyed angling with commercial fishermen who were sport angling guides as avocation, and 11.8 % went with guide other than commercial fishermen, mostly as vocation. In terms of the use of boat, 40.2 % of the total went angling with boat. Of them, 40 % went angling with commercial fishermen who were engaged in sport fishing guide as side business used their own fishing vessels, and 18 % used guide boats which owners were other than commercial fishermen. And remaining 42 % went angling mainly with private boats. Private boat anglers are now showing the increase.

Table 7 shows No. of sport fishing guide by operation. About 88 % of the total were commercial fishermen or FCAs which were organized by local commercial fishermen.

As the No. of coastal fishery households were 180.4 thousands in 1988 (Fishery Census), 13.6 % of them were engaged in sport fishing guide as side business. (It is estimated that almost of all sport fishing guide operated by fishermen are coastal fishery household.)

## 2. REGIMES OF COMMERCIAL FISHERIES AND SPORT FISHING

Japan's fishery regime is unique mainly based on Fishery Law and Fishery Resources Conservation Law. In Japan commercial fisheries are classified into three categories; Free Fishery, Fishing Right Fishery and Fishing License Fishery. Free Fishery which is available for all peoples, is limited the use of fishing gears, only for hook and line and etc., and has not so large effect on the resources. Fishing Right Fishery which can use a certain water area exclusively, is subdivided into Common Fishing Right, Aquaculture Right and Set Net Right. Of them Common Fishing Right is granted only to local FCAs and Set Net Right and some kinds of Aquaculture Right are granted to local FCAs preferentially. That is, local FCAs are permitted to a large degree to manage coastal fisheries which occupy the coastal fishing grounds, such as capture of coastal demersal species, aquaculture and set net fisheries, to assure the life of small scale coastal fishermen.

Local FCA is also pivot for economic activities of fisheries communities through fish marketing business, supply business, banking business and so on. Thus local FCAs are nucleus of coastal fishermen, and only members of FCAs can operate coastal fisheries in fact.

Fishery License Fisheries are for offshore and far sea fisheries, and the licenses are issued by the Minister or prefectural governor, under certain conditions defined for each type of fisheries, such as No. of fishing vessels, vessel size, fishing area, fishing season and etc.

Thus basic fishery management system in Japan is differ from other developed countries. Fishery regime in many developed countries put emphasis on the optimum utilization of the resources based on free access and catch limit, but that in Japan give priority to the management of fishing grounds. For this purpose, the management for the utilization and the conservation in near shore waters is mainly entrusted to local FCAs, and in offshore and far sea waters the emphasis is put on not only the conservation of resources but also the stabilization of fisheries operation and the coordination among fisheries. Further fisheries regime in Japan intends to keep its dual structure, coastal fisheries by households and capitalized fisheries in offshore and far sea waters.

On the other hand, there is no law originally aiming at sport fishing in Japan. But through the popularization of sport fishing and the increase of conflicts between commercial fisheries and sport fishing, it has been taken measures from the side of commercial fishery regime. These measures can be divided into three, measures to regulate sport fishing or to coordinate with commercial fisheries, measures to introduce sport fishing business into commercial fishery, and measures for the safety of vessels which are used to sport fishing guides.

### *2.1 Measures to regulate sport fishing or to coordinate with commercial fisheries*

(i) Prefectural Fisheries Regulation

This Regulation which are set by prefectural governor under the provisions of Fishery Law and Fishery Resources Conservation Law, are originally stipulated to commercial fisheries, but also applicable to sport fishing. By this, sport fishermen are regulated the use of many gears and the catch of demersal inshore resources such as lobster and abalone, but in brief anglings used hook and line are not regulated in sea waters.

(ii) Indication by Fishery Regulatory Commission

This Commission are established by Fishery Law for the coordination between commercial fisheries, but can indicate the coordination scheme between commercial fisheries and sport fishing.

(iii) Notification by the Secretary of Fishery Agency in 1970

The Secretary notified in 1970 to establish Fishing Ground Utilization Coordination Council, composed of commercial fishermen, sport fishermen and academic experts, as an arm of Fishery Regulatory Commission, to deliberate on problems between commercial fisheries and sport fishing for the prevention of conflicts and the peaceful use of fishing grounds. By this notification, each prefecture established the Council.

(iv) Notification by the Secretary of Fishery Agency in 1972

The Secretary notified in 1972 the standard examples to be coordinated by prefectural Fisheries Regulation and Fishery Regulatory Commission.

(v) Amendment of Coastal Fishing Ground Improvement and Development Law (CFGIDL) in 1983

The basic purposes of this law are to contribute to the stable development of coastal fisheries and to the increase of the supply through the propagation of fisheries resources and the improvement of the productivity. The amendment in 1983 added provisions of Fishing Ground Utilization Agreement among users including sport fishermen.

(iv) Amendment of Marine Fisheries Resources Development Law in 1990

This law originally aims the establishment of survey system for the exploitation of fisheries resources, the sound development of fisheries, the stable supply of fisheries products and the rational utilization of fisheries resources. The

amendment in 1990 added provisions that commercial fishermen, sport fishermen, FCAs and federated FCAs can initiatively conclude Resources Management Agreement with one another over a certain resources at a certain fishing ground.

### *2.2 Measures to introduce sport fishing business into commercial fisheries*

(i) Amendment of Fisheries Cooperative Association law in 1990

This law is very important, as described before, for the initiative management of coastal fisheries by FCA. The amendment in 1990 permitted that FCA itself can operate sport angling business and other water dependent marine recreational business, and allowed to sport angling guides other than commercial fishermen to participate into FCA as associate member.

(ii)Amendment of Fishing Port Law in 1988

In Japan fishing port are separated from common port by Common Port Law and Fishing Port Law, and there are about 1,000 common ports and about 3,000 fishing ports. Fishing ports are basically utilized for fisheries exclusively. By this amendment, it became possible in fishing ports to construct water dependent marine recreational facilities such as marina and artificial beach and etc., and to moor sport fishing guide boats which owners are not commercial fishermen.

### *2.3 Measures for the safety of boats used for the sport fishing guide*

Enactment of Sport Fishing Guide Vessel Rationalization Law in 1989

This law was enacted for the safety operation of sport fishing guide vessels, the sound development of this business and the improvement of user facilities, after a sad crash accident between a submarine and a sport fishing guide vessel at Tokyo Bay.

## 3. EXAMPLES AT OMAEZAKI, SHIZUOKA PREFECTURE

Author researched many cases about the relations between commercial fisheries and other water dependent activities. This is one of cases to review how the measures described above worked.

Omaezaki located at the western end of Suruga Bay, is one of large bases for commercial fisheries in the prefecture as well as sight-seeing resort and port town. (see Fig.1)

The commercial fisheries is wide from coastal to far sea, and the landings in recent years are 20,000 to 25,000 tons. Of them about 70 % comes from far sea hook and line skipjack fishing. No. of fishery establishment are 128 and 102 of them are coastal fishery establishments that operate boats less than 10 gross tons. Thus the fishery largely depends on far sea fisheries in landing volume, but in terms of establishment, 80 % depends on coastal fisheries.

Kinsu, a shallow water area about 30km south from Omaezaki, has been used as a good fishing ground for commercial anglingfishermen at Omaezaki and the environs.

The conflict occurred in July 1983 when the first sport fishing guide vessels came to this shallows from Izu Peninsula, another side of Suruga Bay. Local fishermen strongly opposed to this invasion and they requested to Shizuoka Fishery Regulatory Commission that the Commission give a guidance to sport fishing guide vessels from Izu to stop the operation at Kinsu. The prefectural Commission tried the coordination between both groups, but the conflict did not settled. Then the Commission entrusted Shizuoka Fishing Ground Utilization Coordination Council with the solution. The Council consulted with representatives of both parties and an agreement was concluded in Nov. 1983. That is, centered to prefectural Fishing Ground Utilization Coordination Council which is established by a notification of Secretary of Fishery Agency, as an arm of prefectural Regulatory Commission, both parties concluded Fishing Ground Utilization Agreement which was provided in the amendment of CFGIDL.

When the first agreement was contracted, the party of sport fishing guide vessels operation was only one group, Izu Fishing Tour Association and the main conditions were as follows.

| | |
|---|---|
| Fishing season | : from June 15 to Sept. 30 (in Sept., only Sunday and holiday were possible) |
| Fishing hours | : from sunrise to sunset |
| Fishing area | : Kinsu shallow than 200m |
| No. of vessels per one day | : less than 14 vessels |

After then the party of sport fishing guide vessel operation increased to eight groups by 1991, and the conditions were modified through yearly renewal of the agreement.

The conditions in 1991 were as follows.

| | |
|---|---|
| Fishing season | : illustrated in Fig.2 |
| Fishing hours | : from 6:00 to 13:00 (Apr. to Oct.)<br>from 7:00 to 13:00 (Nov. to Mar.) |
| Fishing area | : illustrated in Fig.2 |
| No. of vessels per one day | : eliminated from the agreement |

Another change is that coastal commercial fishermen at Omaezaki and the environs who opposed the sport fishing use of Kinsu at the beginning, introduced the sport fishing guide business as side business. In 1991 No. of sport fishing guides at Omaezaki was accounted for 96, and all of them were coastal fisheries establishments using power vessels less than 10 gross tons. This means that most coastal fishery establishments at Omaezaki conduct sport fishing guide business and they become members of both side of parties, coastal commercial fishery and sport fishing guide operation.

Author estimates that about 2.4 million yen, about one third to one fourth of their total annual income, now come from this guide business at Omaezaki

In these situations Omaezaki FCA established Sport Fishing Section in the organization to promote sport fishing business and to discuss problems.

Further Omaezaki FCA began to collect 3 % of sport fishing boat guide fee from the members. This charge is mainly to make up for the cost of released pelagic fish fry such as red sea bream by the FCA, because sport fishermen angled for the adults. Such charges are becoming common where the release of pelagic fish fry is conducted.

## 4. CONCLUSION

Sport fishing is one of, but most popular, water dependent citizen's activities, not industrial activities and competes with commercial fisheries, because they take the same resources and use same fishing grounds. However they can cooperate through the guide and guest-house business and etc.

As investigated above, the conflicts between commercial fisheries and sport fishing have been settled in general under the framework of the fishery regime. And many coastal commercial fishermen, particularly living in urban areas or sight-seeing areas, introduced the guide business as avocation for the economic vitalization. Such competition and cooperation implies not only underlying issues between commercial fisheries and sport fishing, but also more basic issues how to coordinate the fishery use and other uses of waters, or how to position fisheries management into coastal zone management.

In Japan there is no comprehensive law for the coastal zone management such as CZMA (Coastal Zone Management Act) in the U.S. But 4th NCDP(National Comprehensive Development Plan), a basic land use and conservation plan in Japan, provided the formation of CZMP (Coastal Zone Management Program) by prefecture under the guideline by central Government.

The right of coastal fisheries, one of the utilization of coastal waters, have been recognized traditionally as very strong right compared with other rights in Japan. For instance it is necessary the advanced approval by commercial fishermen concerned for the application of other water dependent projects such as land reclamation, mining, draining of warmed water from electric power station and etc., and in most cases an amount of compensation was payed to commercial fishermen in return for lost income to get the approval. It is also fact that commercial fishermen and their FCA have been kept the coastal environment for their livelihood.

But many citizens and environmentalists began to have questions over the privilege of coastal fisheries and about whose is coastal waters and the renewable resources.

On the other hand, there is no way to collect the fee to make up for the releasing cost by FCAs directly from sport fishermen who don't use guide vessels.

It is expected that water dependent activities by citizen will become more popular, and that sport anglings without guide and the release of fish fry will show more future growth. It is very important to sustain coastal fisheries not only for coastal fishermen and for the supply of fishery products, but also for the protection of coastal environment.

To settle questions by citizen and the problems of commercial fisheries, and to root coastal fisheries in CZMP deeply, it is necessary to get consensus from citizens about the force preserving coastal environments by commercial fishermen and their FCAs, and the importance of the utilization and the management of renewable coastal living resources. Finally it will be needed the comprehensive CZM law which places the priority on the use of renewable resources, not based on the traditional right of coastal fisheries, so that citizen can entrust cost-effectively the management of coastal waters to coastal fishermen and their FCAs.

# Subsistence Fisheries in Alaska : Conflicts Within a Multiple Use Resource

**Hans T. Geier, Joshua A. Greenberg and Mark Herrmann** *

Department of Resource Management, University of Alaska Fairbanks, Fairbanks, AK 99775-0100, USA

ABSTRACT

*Subsistence is the customary and traditional noncommercial uses of renewable natural resources in Alaska. Subsistence is seen as a lifestyle, rather than the simple use of resources. The area of focus is the interior terminal chum salmon fishery along the Yukon and Kuskokwim River drainages. Regulation of the fishery by state agencies and regulatory boards is examined with relation to authority granted by state and federal authorities. Conflicts with commercial fisheries, in the Yukon and Kuskokwim River drainages, and particularly with the intercept mixed-stock salmon fleet at False Pass are described. Future valuation and economic analysis of regional activities to describe accurately the contribution to the interior Alaskan economy of the terminal stream chum salmon subsistence and commercial industries in a regional model is discussed.*

## 1. INTRODUCTION

During the 1980s 110,000 people in 225 Alaskan communities participated in subsistence harvest of resources. This F number has been expanded through a recent Alaskan Supreme Court decision (McDowell v. State). Subsistence, defined as the customary and traditional noncommercial uses of natural resources, is an important component of the culture, traditions, and local economies of many Alaskan communities. Subsistence harvests are widely distributed both intra- and inter-community through kinship and non-monetary market networks. As defined under state regulation, subsistence harvest precludes both commercial and sport harvest of natural resources. The purpose of this paper is to investigate economic and political issues surrounding the chum salmon subsistence fishery in the Yukon River drainage in interior Alaska, to analyze the issues with relation to regulating agencies, and to emphasize the impact of current policy on rural economies.

* This report is the result of research sponsored by Alaska Sea Grant with funds from the National Oceanic and Atmospheric Administration, Office of the Sea Grant, Department of Commerce, under grant no. NA90AA-D-SG066, Project # M/81-01, and with funds from the University of Alaska with funds appropriated by the state.

## 2. SUBSISTENCE AND FISHERIES REGULATION IN ALASKA

Subsistence in Alaska is stated as a rural preference and is defined as an interest, rather than a native right accompanying aboriginal claims, as in Canada (Feit, 1990). Because there is no right to the resource by certain cultural groups, it is not easy to assign property rights or transfer rights through market mechanisms. Only in the Marine Mammal Protection Act is there a definite recognition of wildlife as a component of the subsistence economy essential to the Native way of life (Marine Mammal Protection Act, 1972). Even here, use of products is strictly governed, allowing only minimal development of markets (Katelnikoff v. U.S. 1991). Subsistence is defined in Alaskan law as :

> *"customary and traditional uses in Alaska of wild renewable resources for direct personal or family consumption, as food, shelter, fuel, clothing, tools, or transportation, for the making and selling of handicraft articles out of non-edible by-products of fish and wildlife resources taken for personal or family consumption, and for the customary trade, barter or sharing for personal or family consumption..." (AS16.05.940(23)).*

Two federal laws are applicable to native rights and subsistence use. The Alaska Native Claims Settlement Act (ANCSA) extinguished native property claims to most of Alaska along with subsistence rights, with lands being given to village and regional native corporations. These lands were not sufficient to provide for native subsistence activities, but provided clear title to the land itself. The Alaska National Interest Lands Conservation Act (ANILCA) defined subsistence practices within a rural context, rather than native context, and provided for them on federal lands.

The Alaska Department of Fish and Game (ADF) regulates subsistence hunting and fishing on lands and waters subject to state management. In 1989, the Alaskan Supreme Court struck down the state rural preference for subsistence as unconstitutional (McDowell, 1989) because of the common use clause in the Alaska State Constitution. ADF management of subsistence practices on federal lands in Alaska has been discontinued when federal agencies decided state management was inconsistent with ANILCA. ADF has continued to manage subsistence, sport, and commercial fishing because the state has jurisdiction over all navigable waters, even on federal lands. Additionally, the jurisdiction is extended 12 miles from the low tide mark offshore (Jacobson et. al., 1985). The stated order of regulation is commercial, sport, and finally subsistence. Where there are natural and healthy populations, according to ANILCA, there can be no regulation of subsistence.

The application of ANILCA to fisheries has not yet been recognized by court cases. However, the same order of preference for management of use of fisheries is recognized by ADF Therefore, subsistence has the highest priority, sport second, and commercial last. Two other sections in the Alaska State Constitution pertaining to the management of fisheries are as follows :

> **Section 4-Sustained Yield.**
>
> *"Fish, forests, wildlife, grasslands, and all other replenishable resources belonging to the State shall be utilized, developed, and maintained on the sustained yield principle subject to preferences among beneficial uses."*
>
> **Section 15-No Exclusive Right of Fishery.**
>
> *No exclusive right or special privilege shall be created or authorized in the natural waters of the State. This section does not restrict the power of the State to limit entry into any fishery for purposes of resource conservation, to prevent economic distress among fishers and those dependent upon them for a livelihood and to promote the efficient development of aquaculture in the state. [Amendment approved August 22, 1972-effective October 14, 1972] (Alaska State Constitution).*

Two main conflicts associated with subsistence use of chum salmon in interior Alaska have recently been before the main regulatory body for Alaska State fisheries, the Alaska Board of Fisheries (Board of Fisheries). The two conflicts are : raising the chum cap for the False Pass intercept salmon fishery, and banning of feeding of subsistence salmon to dogs used in commercial endeavors. The subsistence fishery that is threatened is in the Yukon and Kuskokwim River drainages in interior Alaska, extending from the Bering Sea into Canada (Figure 1). While explicitly these conflicts do not directly address the subsistence fishery, the prescribed resolution to these conflicts may weaken subsistence use, and strengthen commercial use.

## 3. COMMERCIAL VS. SUBSISTENCE WITHIN THE FISHERY : DOGS

The largely native subsistence and commercial terminal stream users of chum salmon are located in interior Alaska (and also in Canada) along the Yukon and Kuskokwim rivers, and in the Norton and Kotzebue areas of western Alaska.

Subsistence caught chum salmon are used 70-80 % for dog food, and is appropriately nicknamed "dog salmon". Commercially caught chum salmon in interior fisheries is stripped of its roe for caviar, processed into commercial food goods (McCormick, 1992), and processed as food for dogs (Anderson, 1992).

Dog teams are an integral part of interior Alaskan subsistence lifestyle. They are used for hunting, wood and water hauling, general winter transportation, and also for recreation. Dog racing and trapping are semi-commercial activities that are prevalent in subsistence users' lifestyles (Anderson, 1992).

The use and function of dogs is indicative of how native and subsistence use of resources has changed. Dogs were once the main source of winter transportation and were integral to the subsistence and commercial economy in rural Alaska. Dogs were used to pull sleds for coastal Eskimos up to 1500 years ago and as pack animals by Athabascans in the interior prior to contact by Europeans. Through the fur trading periods, gold rush, and after, dogs served commercial and traditional roles for Natives and non-Natives alike. Starting in the 1930s, airplanes began replacing them for freight and mail. Starting in the 1960s, snowmobiles supplemented and substituted for dog teams, but did not replace them. During the 1970s the limitations and financial obligations of maintaining a snowmachine were realized by some rural residents. It was difficult for those with limited cash income to buy, operate and maintain one. Some residents returned to dogs as a major source of transportation, due to both preference and necessity. Throughout their history, the main food source for dog teams in interior Alaska has been dried fish, of which chum salmon was the most important (Anderson, 1992). Dogs remain an important part of the rural subsistence lifestyle, keeping alive cultural and traditional ways.

A petition to the Alaska Board of Fisheries in late 1990, to prohibit subsistence caught salmon in the Yukon River drainage for dog food in commercial kennels, was initiated in the village of Russian Mission. The initiators of the petition had competing commercial fishery interests. An attorney general opinion cited in the petition held that "feeding subsistence caught fish to dog teams used...primarily for a non-subsistence use, such as commercial racing... probably does not qualify for subsistence use." The Board of Fisheries took action on the petition and broadened its scope in Proposal 396 to include statewide prohibition of the use of subsistence-caught fish to feed dogs used for commercial purposes including dog racing, commercial kennels, and trapping for fur sales (Anderson, 1992).

ADF Division of Subsistence completed a study in January 1992 to collect information on past and present uses of dog teams, and the role that fish play in feeding them, in the Yukon River Drainage. Study results emphasized that "sled dogs remain part of a whole sphere of activities that is actively encouraged as an alternative to idleness, unemployment, and substance abuse" in rural Alaska for communities and individuals. Subsistence caught fish are an important component of the diet of dogs in smaller kennels in most areas. Commercially caught chum salmon for roe are also used for dog food in other areas, as well as the subsistence catch. Large commercial racing kennels were found conclusively to use high protein, high energy commercial dog food as opposed to subsistence fish (Anderson, 1992). The State Board of Fisheries has decided not to enact Proposal 396.

The commercial fishers in the Yukon River drainage fishery were frustrated at the time the petition was filed because of closure of commercial fisheries due to declining salmon stocks. Subsistence permit holders continued to fish. Some of these individuals also held commercial permits. Abuse of the subsistence privilege was perceived to be widespread by commercial terminal stream fishers. Accordingly, there was great frustration among competing users in the same fishery. The petition arose as a consequence of this frustration. After the petition was filed with the Board of Fisheries, it became apparent that most subsistence fishers were also commercial fishers. Frequently, revenues from commercial activities supported subsistence activities. Therefore, the petition to the Board of Fisheries pitted a large portion of the Yukon River drainage fishers with common interests against each other. Reevaluation of the fishery conflict directed the subsistence and commercial terminal stream users to a threat viewed in common, the False Pass commercial intercept fishery (McCormick, 1992 ; Umphenour, 1992).

## 4. THE FALSE PASS COMMERCIAL INTERCEPT FISHERY VS. INTERIOR SUBSISTENCE AND COMMERCIAL TERMINAL STREAM FISHERIES

The False Pass area at the end of the Alaskan Peninsula in Southwest Alaska plays host to an intercept fisheries' fleet. Salmon migrating to western Alaska migrate around Unimak Island off of the Aleutian Peninsula and continue north. Thus, this area near False Pass is a natural congregation point (Figure 1). The False Pass intercept fleet's main target is

sockeye salmon. Sockeye salmon are a high valued species, mainly exported to Japan. In contrast, chum salmon are a relatively low valued salmon species. Chum salmon is a bycatch of the sockeye salmon harvest. The chum salmon cap imposed by the Board of Fisheries forces the False Pass commercial fleet to limit their catches of sockeye salmon. The fishery is closed once the bycatch limit of chum salmon is reached. Therefore, they want the chum salmon cap to be as high as possible to maximize their landings of the more commercially lucrative sockeye salmon.

Commercial salmon fishing at False Pass is by set net (113 permanent permits issued), purse seine (119 permits), and drift gill nets (158 permits). Additional interim use permits were issued. The distribution of the permits for salmon in the False Pass area to non-residents in 1990 were 17, 23, and 44 percent respectively. Permits held by Alaskan residents were concentrated in the less productive set net category. Set net harvests average only about half that of the purse seine and drift gill nets. Non-residents are increasing their share of permits in the fishery (Commercial Fisheries Entry Commission, 1992).

There were 393 total permits fished in 1990 in the False Pass fishery, with reported landings of 51,248,790 pounds. The average harvest per permit was 130,404 pounds (Commercial Fisheries Entry Commission, 1992). The False Pass fishers are heavily capitalized with large investments in vessels and gear. The primary market for harvested sockeye salmon is Japan.

In the commercial Western Alaska interior terminal stream fishery, there was a total of 17,041,796 pounds of fish caught by 1923 permit holders (23, or 1.2 % were non-residents) in 1990 for an average of 8,862 pounds per permit (Commercial Fisheries Entry Commission, 1992). The scale of the commercial fisheries is small and permit holders often have a subsistence permit as well. Subsistence has become increasingly capital intensive as competition for resources increased. The existence of commercial interior fisheries and processing is one of the few entrepreneurial ways for interior Alaskan residents to obtain cash income to purchase gear and equipment for subsistence fishing, hunting, and other activities. Commercially harvested fish from these fisheries is primarily allocated to instate markets, with limited exports, primarily of roe and high quality chum salmon to Japan. Reduction of the terminal stream portion of the harvest of the western Alaskan fishery is feared by residents because the absence of alternative sources of cash income. Rural residents believe this would lead to increased dependence on state and federal welfare and social programs, and impede their ability to participate in subsistence practices.

Thus, the conflict between the False Pass intercept fishery and the terminal stream users shapes up as a "big boys against little boys" conflict (McCormick, 1992). Smaller numbers of highly capitalized commercial fishers on one hand, and traditional, small scale fishers on the other set the stage for a bitter political battle which has been administered by the Board of Fisheries, and is now moving into the courts (Elim v. State, 1992). The interior fishers on the Yukon, Koyukon, and Kuskokwim rivers interest is the chum salmon. They believe the incidental catch by western Alaska mixed-stock intercept fisheries is the reason for recent low harvests. Any chum cap above 400,000 is viewed as detrimental to Yukon River fisheries (Yaska, 1992). Therefore, they are taking action to relieve pressure on the fishery from the False Pass intercept fleet.

The State of Alaska Board of Fisheries, in November 1991 set the 1992 False Pass chum cap at 900,000, 50 % more than the 1991 season allowance of 600,000. The reaction from Yukon and Kuskokwim River fishers was swift and sure. Lawsuits were threatened, and accusations of special interests and politics abounded. Terminal stream users wanted a cap of 400,000, 200,000 less than in 1991. In December it was found that the study the Board of Fisheries based its chum cap on contained a statistical error. The Board decided to reconsider, and on March 16 rolled back the False Pass chum cap to 700,000.

The Alaska Department of Fish and Game Division of Commercial Fisheries published the study that the Board of Fisheries based its initial False Pass 1992 chum cap decision (Eggers, et. al., 1991). The study was roundly criticized for questionable research methodologies in an internal ADF peer review (ADF Memo 121291.MEM, 1991). A statistical inaccuracy was also found. Similar questions were raised by external review (Rexstad, 1991), and in general by resource users and others familiar with the study, its methodologies, and the fisheries.

Even before the statistical error was detected, the study was subject to severe criticism by interior Alaskan Native interests, and commercial and subsistence fisheries interests (Hilsinger, 1991). Questions regarding the efficacy of the study include :

i) The study only covers one year. ADF biologists recommend that to be accurate, a study must cover the entire life cycle of a fish, or at least 4 years for chum salmon.

ii) Fish were tagged by the fleet that fished for them--interior fishers felt this led to a conflict of interests. Objectivity was called into question by this.

iii) Only 40 % (6,300 out of a targeted 15,000) of the desired number of fish were tagged.

iv) The fish were not tagged during the originally planned time frame, and the commercial fishery opening occurred the day after tagging ended. 30 % of the reduced number of tagged fish were caught during the opening.

v) 5.There was no commercial fishing along the Yukon River drainage in 1987. If there was a commercial season, the harvest would have been much higher. Therefore, this sample population was not accounted for.

vi) 6.Fishers in remote areas, including in Canada, were not notified of the study, leading to low return of tags.

Additional questions concerning methodological techniques were raised, including the decision of the author not to use certain tagged fish, combination of several susceptible salmon runs, and inadequate ground surveys by ADF (Hilsinger, 1991 ; McCormick, 1992 ; Umphenour, 1992).

Native subsistence users in the Yukon River drainage were especially critical of the tagging method used in the study, saying that tagged fish that did make it up the Yukon were weak and sickly (Yaska, 1992). The implication was that stress from tagging reduced their ability to return up the river, and thus lowered the return for spawning Yukon River salmon tagged at False Pass. The native fishers in interior Alaska state that they have been able to detect a difference in return in years with high chum caps at False Pass. Graphical examination of ADF data supports this contention, though statistical analysis has not been pursued except in the 1987 ADF study.

The chum stocks in western Alaska and in the Yukon and Kuskokwim River drainages have been in severe decline. Fishers in these areas have been taking severe conservation efforts, but concurrently the intercept fishery has been increasing its take of the bycatch chum. The Native and non-Native community (50,000 people) in western Alaska is represented by The Western Interior Fisheries Coalition. This organization has targeted all future Board of Fisheries proceedings that regulate Alaskan intercept fisheries. It has issued a strong statement of intent against what it sees as a four vote majority representation of the intercept fisheries. The political ramifications of this issue promise to be lengthy and bitter (Naneng, 1992). Additionally, the Alaskan Federation of Natives has filed a countersuit to a state lawsuit against federal government subsistence policies in Alaska. This underscores a distrust of Alaskan Natives for state regulation of subsistence (Hulen, 1992). Subsistence fisheries issues, as well as commercial allocation in interior Alaska will be central to the arguments that the Board of Fisheries will have to consider. The regulation of Alaska's fisheries, dictated first by biological statutes of sustained yield, and second by allocation to subsistence use, will provide the core of the opposition to chum caps in the False Pass intercept fishery.

## 5. TWO THREATS, DIFFERENT ISSUES, A DEPLETED RESOURCE

There are thus two threats to the interests of subsistence fishers in interior Alaskan fisheries posed by Alaska Board of Fisheries decisions. The first is the threat to the predominant subsistence use of the resource, and second, an increase of the bycatch of the intercept commercial fleet in the False Pass fishery area which is believed to be depleting the resource. Both threats were initiated by competing commercial interests for the resource. The first was initiated by a commercial interest which was in direct competition in the area of the fishery, at a time when there was very limited fishing allowed. Reconciliation of the parties has occurred, and they have united to address the outside threat against their combined interests. It appears the Alaska Board of Fisheries has shown a preference for the interests of commercial users of the resource outside of the area of origination of the fishery, and subsistence and commercial users in interior Alaska have had the burden of proof placed upon them.

The Alaska Constitution, ANILCA, and ADF regulations specify sustained yield management (ANILCA specifies "natural and healthy"), and then a preference for subsistence use. In regulating a resource, the state or federal agencies must regulate commercial use first, sport use second, and subsistence use last. The False Pass decision is viewed by rural interior interest groups as having violated the Alaska state and federal provisions by allocating the resource to commercial users over subsistence users--to intercept fleets over terminal stream users--as well as jeopardizing biological diversity (Naneng, 1992). The Alaska Constitutional provisions for management of fisheries and other natural resources,

the federal management provision in ANILCA for "natural and healthy populations" and those federal laws governing endangered and threatened species have the potential to be triggered by the actions of the Board of Fisheries in the case of False Pass.

While the Board of Fisheries did not pass the resolution banning the use of subsistence fish by commercial kennels, the intent by commercial fishers appeared to be to limit demand for the resource. Protection of interior Alaskan subsistence and commercial fishers interests by the Board of Fisheries is perceived by them to be inadequate. An adversarial relationship has been established between the Alaskan Board of Fisheries, and western interior Alaskan fishers, Native interest groups, and dog mushers. Future conflict resolution will be tainted by this relationship.

## 6. IMPLICATIONS FOR RESEARCH

The interior fisheries provide both monetary and non-monetary returns. Subsistence harvest, by definition, is non-commercial, and therefore not traded in formal markets. Thus, there is no market clearing price upon which to base estimates of benefits from subsistence activities. Additionally, while commercial harvest in the interior is sold in markets, these returns do not fully capture its benefits. Revenues from commercial harvest support the subsistence lifestyle of interior state residents. Decreases in commercial harvest may severely limit the ability of interior residents to maintain subsistence practices. Economic techniques for valuing non-market commodities, such as contingent evaluation, are inadequate in this case (Brown and Burch, 1989). Evaluation of activities on a regional basis, with relation to interfaces with the market economy, time and labor involved, inputs, and final consumption is needed to accurately describe the nonmarket, subsistence part of the economy, and the impact of changes to it.

In cases of regulation by a governing board, there are clear delineations of political and economic interests affected by resource use decisions. What is not clear is quantification of economic impact of the decisions. Immediate impact to affected parties can be easily estimated, but total effects to regional economies are not so simply calculated. The subsistence economy in interior Alaska has been studied by social scientists, including economic anthropologists and economists (Ellana and Wheeler, 1989 ; Langdon, 1984 ; Lonner, 1980). However, a comprehensive economic database has not been derived for regional analysis for impact studies on the interior subsistence and noncash economy. Because of this lack of data, accurate impact analysis is not possible.

We are currently initiating a study to gather data to construct a database for input-output regional economic analysis using IMPLAN software. The incorporation of the subsistence economy in the Yukon-Koyukuk Census region in interior Alaska is the immediate priority of the study. Past economic studies in Alaska have been limited in scope, or lacked sufficient detail to capture the unique structure of rural Alaskan economies. Research has focused primarily on single resource development issues, failing to incorporate interrelationships which exist between various sectors within regional economies, especially subsistence. These limitations are due primarily to the absence of an adequate database upon which to base more comprehensive economic analysis.

Subsistence activities include commodity production, processing and manufacturing activities, distribution, and consumption of regional products. Alaska's economy in general resembles that of a developing country. It's cash component is based on resource extraction and services. For the monetized economy, almost all manufactured goods are imported, and raw materials are exported. There is a distinct lack of entrepreneurial activity in Alaska. Interior commercial fish processing is one example, and subsistence use is a distinct economic activity involving economic resources for regional use by local residents. Thus, most currently measured economic activity in rural Alaska is expected to have a very low multiplier because of the loss of production revenue to Outside. Subsistence activities are very different from most monetized activities because their products are almost exclusively produced, processed, and consumed locally. Our future research on this topic is expected to show comparatively high multipliers for subsistence economic activity, and also those activities that are linked closely to local production, compared to competing extractive uses of resources for export.

Future regional economic research in Alaska will be necessary to accurately describe impacts that government policies, economic development, or competing economic activities will have upon local economies. The description of subsistence activities in an input-output framework will provide a firm foundation upon which to base future natural resource management decisions in Alaska. Resource conflicts will more accurately be reflected by being able to analyze total

economic activity and linkages in the interior Alaskan economy. Replacement of subsistence fish will be costly in terms of substitution of imported food and dog food. Commercial fisheries are also affected. The full economic effect on interior Alaskan economies due to economic linkages and multipliers will be substantial. Accurate economic data and input-output modeling will provide needed documentation of the importance of interior Alaskan fisheries to industries, communities, and individuals.

ABSTRACT

*In order to manage effectively those fisheries being exploited by both commercial and recreational interests, regulatory agencies require a wider range of information than that needed for solely commercial fisheries. Methodologies have been developed and applied in North America and elsewhere to provide information on such fisheries but until recently European regulatory agencies have not normally incorporated information on recreational sectors in making choices on regulatory frameworks and policies, except perhaps in the management of anadromous stocks such as salmon.*

*This paper analyzes developments in the UK in connection with the marine fishery for sea bass (Dicentrarchus labrax), a fishery which provides both significant income opportunities for commercial fishermen as well as being the basis for one of the most highly regarded recreational fisheries. The authors have undertaken work in conjunction with the UK regulatory agency (the Ministry for Agriculture, Fisheries and Food) in developing relevant quantitative and qualitative data concerning both sectors of the fishery. In particular, the paper outlines work undertaken to generate economic data concerning the recreational sector of the fishery, the first time that such information has been gathered as an input into marine fisheries management in the UK.*

*Partly in the light of the information generated, the regulatory agency has increased the scope of its management measures to apply to recreational as well as commercial fishing interests. This demonstrates an increasing awareness by*

*the UK regulatory agency both of the economic (and biological) significance of recreational fishing, and also of the need to consider a wider range of information when choosing management objectives and techniques for jointly exploited fisheries.*

## 1. INTRODUCTION

Throughout the world, marine fish stocks are being threatened by commercial fishing. In many areas, exploitation of these stocks is being increased by the growth of recreational fishing as a leisure activity. This growth is associated with factors such as increases in leisure time, personal disposable incomes, participant mobility and in the appreciation of environmental qualities. Yet only in relatively few countries is explicit attention being paid to these recreational fisheries, and even in countries with rather sophisticated fisheries management regimes, the significance of recreational activities may be unknown or disregarded.

Hence, whilst countries like the USA and Australia are conspicuous examples of where fisheries management authorities seek to pay particular regard to marine recreational fisheries within the broader framework, in the UK almost no attention is paid to the recreational sector, save in the important exception of salmonid fisheries. This has been the case, even where commercial and recreational fisheries have been in direct competition. Only in the last few years have such considerations begun to play a part, and this has rapidly uncovered the absence of almost any reliable information on these fisheries.

This absence is in some ways surprising : biologists are concerned with the joint management of the commercial and recreational sectors of a fishery since the fish mortality caused by recreational fishing needs to be taken into account before scientific advice can be provided to fisheries management authorities. At the most basic level, their calculations and advice will otherwise risk being erroneous ; at another level, increased restrictions on the commercial sector (e.g. by gear, area, etc.) may not prevent depletion of the resource if the recreational sector remains uncontrolled (and indeed, able to benefit from any controls over their commercial competitors). From an economist's viewpoint, if management is to pursue rational objectives, then the "value" of recreational fishing needs to be determined in a form that is comparable with the "value" of commercial fishing at any time when the economic impact of management measures is under debate. At another level, determination of the value of the components of a fishery may well soon become an influence in determining "who pays" for the costs of management.

However, recreational fisheries have traditionally been thought of as insignificant in scale, localised in impact, and economically unimportant. The largely diffused nature of the activity can conceal its size and significance, just as the fishing port emphasises that of the commercial sector. Indeed in some cases management authorities have regarded recreational fishing as being beyond their remit anyway (as being "leisure", or "sport").

Nevertheless, there is clear evidence that recreational fishing is indeed important, in both biological and economic terms. To take a few examples from many possible, Kearney (1991) reports that the tailor fishery in the Richmond River (New South Wales, Australia) shows recreational catches almost a hundred times greater than the commercial landings. In Tasmania, commercial bluefin tuna fishermen tie up their boats at weekends, because the influx of recreational fishermen has made it too difficult and costly to fish (Lal *et al.*, 1991). On the west coast of North America, over 1.2 million coho salmon are caught annually by recreational fishermen, and over 1.5 million kelp bass (NOAA 1990). In Great Britain, recreational landings of salmon are some 38 % of total reported landings in England, Scotland and Wales ; indeed our own recent work has estimated the capitalised total net economic value of these salmon fisheries to be some £340 million (1988 prices), of which the recreational sector contributed 96 % (Radford *et al.*, 1991). We shall later report that we have estimated the recreational catch of sea bass in the UK to be at least as large as the commercial catch.

There can be no doubting the biological and economic significance of marine recreational fishing in a wide range of circumstances internationally, and it is a significance that appears to be growing. This significance has been recognised in the USA, where the Fisheries Conservation and Management Act (1976) made express provision for the allocation of harvests between commercial and recreational interests, and already some Regional Fishery Management Councils are making these allocations. In Australia, some State governments have recently incorporated recreational fishing into their management plans. In Western Australia, for example, all recreational fisheries are now managed by bag limits and three are licensed. In contrast, in the UK and much of Europe, there is no precedent for managing marine recreational fishing, let alone allocating harvests between the sectors. Indeed, little appears to be known about marine recreational fishing at all.

Since 1987 CEMARE have been working with the UK fisheries management agency, the Ministry of Agriculture, Fisheries and Food (MAFF), investigating the joint recreational and commercial fishery for bass. This paper reports on some aspects of our work, and highlights in particular the difficulties of generating significant data which are required information in making informed management decisions, in an environment in which little or no previous work has been conducted.

## 2. ECONOMIC INFORMATION

With regard to the management of fisheries which have a restricted harvest, managers must allocate that harvest, explicitly or implicitly, between user groups. If they ignore any group, then that group can expand its activities to benefit from inhibitions on other groups. The criteria for determining an optimal yield or the optimal levels of effort from both sectors must be based on economic considerations (see for example, McConnell and Sutinen, 1979). Economic information is also needed to evaluate the impact and effectiveness of management measures. The following section considers briefly some economic information that is required by fishery managers, particularly with relevance to recreational fishing.

Edwards (1990) provides a useful brief summary of the relevant economic analysis. The key element lies in the estimation of what Edwards refers to as 'net national benefit', which is perhaps more usually called net economic value. In calculating this net economic value, estimations have to be made concerning both sectors. In each case, there are elements of both consumer and producer surplus to be considered, and estimates of total economic value must always be net of total resource costs. In the seafood sector, there is producer surplus being gained throughout the chain from the fishermen to the retail sector, together with the consumer surplus gained by the fish consumers. In the recreational sector, there is consumer surplus deriving to all the recreational fishermen, together with producer surplus accruing to those involved in the charter fishing element of the sector. In certain cases where private ownership exists, there may also be producer surplus for the resource owner, as for example in the case of UK salmonid fisheries.

When referring to the economic significance of a commercial fishery, it is common practice, however, to talk in terms of the first-hand value of landings (output). This over-estimates the net economic value associated with commercial fishing because resource costs are not subtracted. On the other hand, it disregards other aspects of consumer and producer surplus.

Since recreational fishermen are by definition not fishing for profit, the value of their retained catch (based on current market prices) cannot provide a relevant measure of the economic significance of recreational fishing, where the output is 'recreation', not 'fish caught'. This output is a multi-dimensional concept and involves a wide range of satisfactions : this has been the subject of considerable research, e.g., Stevens (1966), Moeller and Engelken (1972), Bryan (1974), Dawson and Wilkins (1980) and Hudgins (1984). However, as Cunningham *et al.* (1985) conclude, economists concerned with fisheries management are generally forced to make certain assumptions ; they will for example usually assume that the value of recreational fishing will increase with fish density over a relevant range.

How this recreational output is best valued is still the subject of widespread debate. Non-economists may consider the expenditures of recreational fishermen to be a relevant indicator of the "significance" of recreational fishing. Indeed, gross expenditure data are a popular measure, particularly with recreational pressure groups because they tend to produce impressively large figures. Whilst expenditures may have important **economic impact** effects (particularly at the local economy level) and are useful for such studies, they have sometimes been wrongly used as indicators of the **net economic value** of the activity itself in social welfare terms.

The central problem is that a great deal of recreational fishing is a non-market good, although there are some important exceptions. For example, in the UK most fishing rights in the salmon fishery are under private ownership, and most of the economic value is in fact rent (capitalised at £327 million in 1988 : Radford *et al.*,1991, *op. cit.*). Nevertheless for most recreational fishing, in order to make estimates of consumer surplus it is necessary to construct a hypothetical demand curve, employing data from either surrogate or created markets. This enables us in theory to make a first estimate of the net economic value of the recreational fishery, although there may well be other non-consumptive use values and non-use values which should theoretically be included (see for example Bishop, 1987).

Various techniques have been developed to derive monetary estimates for the value of non-priced recreational resources. Stabler (1980) and OECD (1989) provide useful summaries of methods that have been used in the evaluation of the benefits of recreation, and Rockland (1986) provides a comparison of social welfare and economic impact techniques.

The principal measures that have commanded widespread attention are the Travel Cost Method (TCM) and the Contingent Valuation Method (CVM). In the latter, first proposed by Davis (1964), a market is created by questions put to recreationists on their evaluation of the resources they use. Steinhoff *et al.* (1987) summarises by explaining that recreationists may be asked how much they would pay to have a given experience, object or privilege (willingness to pay, WTP), or how much they would have to be paid to give it up (willingness to sell, WTS). In contrast in the TC method, a surrogate market is employed, based primarily on the contention that consumers' responses to travel costs and time can be employed as a surrogate for their response to resource access prices (if they existed).

Both these methods have been severely criticised. Eberle and Hayden (1991) discuss the use of these techniques in valuing natural resources and ecosystems, and encapsulate such criticisms by saying, "the CV and TC approaches lack methodological, theoretical and empirical grounding. Their continued use will mislead valuation attempts and frustrate policy.....". Others take a more positive view : for example, "the travel cost demand model is a useful tool in understanding recreation behaviour and economic aspects of outdoor recreation" (Fletcher *et al.*, 1990 ; see also Smith, 1989). However, no-one would pretend that a wholly acceptable technique for such work yet exists.

Meanwhile, however, fisheries management must proceed : one recalls that admirable fisheries scientist John Gulland calling many years ago for more "quick and dirty biology" as we could not afford to wait for the perfect version. Likewise, economists have a responsibility to input information into conflict situations in fisheries management - albeit, making clear the limitations and reservations attached to the data and analyses.

## 3. THE UK BASS FISHERY

In the waters around the UK, the bass is towards the northern limit of its range, and annual distribution and abundance are determined largely by environmental factors (particularly sea temperatures). In 1972, official MAFF statistics recorded only 21 tonnes of bass landed at major ports. With the development of the market for bass in Europe and the high unit value of bass, the fishery expanded considerably and in 1987 MAFF statistics recorded 125 tonnes landed. The basic point of departure for this investigation was therefore that here was a (very) small fishery, but one highly regarded by inshore fishermen and recreational anglers alike. It seemed likely that it was in reality rather larger than the official data suggested. How big was it ? What were the relative sizes of the commercial and recreational sectors ? How valuable was it to each sector ? Management could not proceed with any confidence without having some answers to these questions.

In 1981, under pressure from recreational interests (for whom bass is the premier marine sport fish), MAFF's Directorate of Fisheries Research (DFR) initiated a research programme aimed at, "providing advice to the Government on the state of bass stocks and the management measures needed to safeguard their future and to maintain a fishery" (Pawson and Pickett, 1987).

This programme investigated the biology of bass and gradually developed a log-book recording scheme for a sample of volunteer bass fishermen to monitor fishing effort and landings - see Pickett (1990) for details. Initially these estimates were probably rather unreliable, due to sampling problems. However, as the quality of the data improved, it soon became apparent that official MAFF statistics significantly under-estimated landings (see Figure 1), mainly because most bass is landed at scattered minor ports which are not included in the MAFF statistics. The programme also estimated there to be significant numbers of recreational fishermen exploiting the fishery. By 1987, the log-book sampling system had become sufficiently robust to suggest with reasonable confidence that true landings were some 785 tonnes - very much higher than the officially recorded data, but including some estimate of recreational landings (though this was based only on charter and other boat angling activities).

In their work, MAFF scientists became increasingly aware of the need to identify some of the economic aspects of the fishery, both in terms of understanding the dynamics of the fishery and as an input into the analysis of management options, particularly concerning the recreational sector. In 1987 MAFF commissioned the Centre for Marine Resource Economics (CEMARE) to undertake an economic evaluation of the bass fishery (see Dunn *et al.*, 1989).

## 4. COMMERCIAL SECTOR

In investigating the commercial sector of the fishery, the first step was to examine and verify the log-book system for estimating commercial landings. This was undertaken, and commercial landings in the study year 1987 were estimated at 630 tonnes. Subsequent work was directed at identifying some of the economic parameters of the fishery by means of questionnaire and interview survey of just over 10 % of the 1,200 boats in the commercial fishery (DFR census data). This concluded, *inter alia*, that the first hand value of the commercial fishery was some £3.9 million, which reflects the high unit value of sales, estimated at £6.19/kg.

Although of interest, this figure is not of course net economic value. As an indicative approximation, it can be estimated that economic rent comprised about 42 % of the gross revenue generated by the commercial bass fishery, giving a figure of £1.6 million. In arriving at this figure it was assumed that for much of the labour employed in the fishery there were limited alternative job opportunities, and accordingly labour was shadow-priced at 50 % of its market value. It should also be noted that the figure of £1.6 million is likely to consist of intra-marginal rent (i.e., producer surplus) rather than resource rent, since the latter will have been largely dissipated on account of the open-access character of this particular fishery. Strictly, total producer surplus for the fishery should also include producer surplus at subsequent stages in the marketing chain, but it was not possible to generate data on this (graph 1).

In addition to producer surplus, we must also consider consumer surplus within the commercial sector. In the UK the bass is a very highly priced fish, much of which goes for export, from which market forces influence UK prices. Much of the remainder is used in restaurants, where it is usually amongst the most expensive fish on the menu. Econometric demand investigations suggested that the demand curve was very flattened, and this was suggestive that consumer surplus in the UK was very low. Again, however, it should be stressed that the estimates which were made of price flexibility with respect to domestic supplies were extremely tentative, owing to the unreliability of the available information on landings data.

Although this work in the commercial sector raised a number of problems of data and analysis, these were overshadowed by difficulties in the recreational sector. Here, the investigation began with no significant information at all, on the size or significance of the fishery.

## 5. RECREATIONAL SECTOR

### *5.1 Methodology*

Marine recreational fishermen in the UK are not required to purchase a licence. There is no register of anglers and only a small proportion belong to fishing clubs - 17 % in 1980 (NOP, 1980). Therefore a direct interview, on-site survey sampling technique provides the only realistic option for analyzing marine recreational fishing.

In addressing the recreational sector of the UK bass fishery, the CEMARE study initially undertook on-site interviews with 487 anglers at 76 representative sites around the coastline of England and Wales (from Norfolk to Cumbria). Personal interviews were conducted on selected sampling units (fishing days) throughout the bass fishing season. This very modest sample set illustrates the problem of undertaking an evaluation where almost no baseline data exists : with little or no other source of information (addresses, etc.) regarding anglers, there was no alternative, even though in the case of bass angling, this presented significant operational difficulties (e.g., isolated locations, night angling, interception of boat anglers, etc.). A stark contrast can be drawn with the Connelly and Brown (1991) study, where an available database permitted the use of 17,000 mailed questionnaires related to freshwater fisheries in New York.

A comprehensive questionnaire was developed for use in the on-site survey, containing questions relating, *inter alia* , to effort, catches and expenditures. To estimate the economic significance of the recreational fishery for bass in the UK, the CEMARE study adopted the CVM in the expectation that this would at least produce upper and lower estimates, using WTP and WTS, even if they were subject to potentially wide and unknown margins of error. The questionnaire therefore included two questions designed to elicit meaningful responses based on hypothetical scenarios which required the anglers to state how much they would have been willing to pay to gain access to bass fishing for one year and how much they would have required in compensation to forego bass fishing for one year. Responses were refined by means of an iterative bidding-game procedure.

Strictly, in addition to consumer surplus, the net economic value of the sector should also include any producer surplus accruing to those involved in it as charter boat operators. Unfortunately, again very little information exists on this sub-sector in the UK, and no reliable estimates were possible.

### *5.2 Results*

Survey results from the questionnaire work were grossed up to census data provided by the 1980 National Angling Survey (NOP, 1980). The CEMARE study estimated there to have been just under 500,000 recreational fishermen participating in the UK bass fishery in 1987. These included some who fished just once, through to "specialist" bass anglers, in some cases fishing for bass as often as 300 times annually. It was estimated that these anglers caught between 660 and 694 tonnes of bass, to be compared with the estimated commercial catch of 630 tonnes.

With regard to the economic significance of the recreational fishery, the study estimated the annual gross expenditure of bass anglers to have been at least £15.8 million. The estimate of the net value of the recreational fishery based on WTP for one year's bass fishing (as estimated employing CVM) was calculated to have been £8.7 million, whilst that based on WTS was some £111.6 million. Such a large divergence is notable, but not without precedent in CVM studies (see for example, Knetsch and Sinden, 1984), and various explanations are possible (see OECD, 1989). The usual reservations for CVM work must be added, particularly that whilst the investigators felt that respondents certainly understood the hypothesis being pursued, it was difficult to tell whether they responded with the same judgements as if faced with the phenomenon in a real situation, and other undetected biases may have been present. The study considered that the WTP estimate did represent a reasonable first approximation to the *minimum* amount of money that would have to be paid to bass anglers to compensate them satisfactorily for a one year closure of the recreational bass fishery.

## 6. SUMMARY

In considering the management of the bass fishery in the UK in the mid-1980s, the management agency faced a situation where it was analyzing a small but developing inshore fishery, highly regarded by both commercial and recreational fishermen. Conflict over the resource was apparent, and pressure groups were pressing for advantage. Commercial landings data were known to be erroneous by a wide (but unknown) margin, there was no information on recreational catches, and no information at all on economic aspects of either sector.

The study being reported here was not able to fill all the gaps, even for 1987 let alone on an on-going basis. However, it did reveal the existence of a recreational sector that was at least as large in terms of landings as the commercial sector. It also suggested that the agency was managing a fishery with a considerable net economic value in recreational use, whilst it was also significant to commercial fishermen because of the high unit value of the catch. The exact data produced were not perhaps in themselves vital, and certainly not totally reliable. However, the study did perhaps demonstrate that relevant and useful data can be generated.

This is a lesson that has already been absorbed and acted upon elsewhere. The UK, and possibly other parts of Europe, are lagging significantly behind countries such as the USA and Australia in recognising the significance of recreational fishing and incorporating it into fisheries management plans. Economic evaluations of joint commercial and recreational fisheries are likely to become increasingly important as fishery managers in the UK and in Europe begin to appreciate the need for economic information relating to both sectors in fisheries management.

In relation to the UK bass fishery, *ex post* evaluations of recreational fisheries in themselves may not provide the fisheries management agency with information that is of use in managing the fishery, but they can provide a basis for *ex ante* evaluations of the impacts of management measures. Having established base values for the UK recreational bass fishery in 1987, it is now possible to assess the impact of the package of management measures introduced in 1990 on both sectors of the fishery (see MAFF, 1990 for details).

In extending the management measures for the UK bass fishery to include recreational as well as commercial fishermen, MAFF have demonstrated an increasing awareness of the economic (and biological) significance of recreational fishing. Management of other marine fisheries would undoubtedly benefit from the input of information regarding recreational fishing.

ABSTRACT

*New Institutional Economics (NIE) includes many theoretical developments in the social sciences which address shortcomings in the neoclassical rational choice paradigm. Certain limitations of economic theory, particularly assumptions pertaining to information and transactions costs (ITCs) and collective behaviour are addressed by this school of thought. NIE appears to be an excellent framework for analyzing problems in development, since economic stagnation may be due in part to high ITCs which preclude not only markets, but many other normally occuring non-market institutions as well. Finally, the NIE provides useful insights into policy design, implementation and enforcement, because it focuses analytical attention on ITC management.The main objectives of this paper are to : 1) Identify applications of NIE to problems in fisheries ; 2) Interpret the implications of NIE for fishery policy, and contrast these policies with those policies which might be suggested with a more orthodox neoclassical approach. Results of a modelling exercise of a fishery in open access underline the reason for and the significance of simple rules. It is argued that these rules can reinforce the endogenous tendencies of the open access system to disrupt itself, when the ITC environment is favourable.*

## 1. INTRODUCTION

"What I am saying, in effect, is that it is not possible to be of much help in policy formation unless analysis is combined with studies of how various kinds of institutions (firms, markets, regulations) actually work in

* Thanks to the students of Micro-économie des ressources maritimes (Fall 1991), to Eduardo Klein Salas for computer assistance and to Anthony Charles for his review. Comments are invited.

The views expressed in this paper are those of the author(s) and do not necessarily represent the official position of the National Marine Fisheries Service or any other Federal Agency

> practice...If this were done, it would become possible to begin to make more useful policy recommendations, and to say whether an institution should be extended, modified or curtailed in favour of some other. These studies of what Heaven is like are not without interest, but they are bound to have most interest for people who are sure of getting there." **R. H. Coase (1970)**[1].

New Institutional Economics (NIE) includes many theoretical developments in the social sciences which address shortcomings in the neo-classical rational choice paradigm. It is an out-growth of institutionalist writers, who tended to take subjectivist approaches to the analysis of economic behaviour, rather than seeking to derive refutable hypotheses from abstract propositions. These approaches, though rich in observation and historical value, uncovered few general mechanisms of individual or collective behaviour, in the opinion of some economic historians. It was not until the landmark works of the Property Rights and Collective Choice authors that there were many refutable hypotheses which could be related to the formation, change and disintegration of institutions. Certain limitations of conventional economic theory, particularly assumptions pertaining to information and collective behaviour were addressed by these authors. Now, there are many good examples of how institutional economics has been re-vitalized by a judicious marriage of the rational choice paradigm, with its power to elegantly produce refutable hypotheses, and the more "bio-sciences" approach of field observation.

However, within the fisheries economics profession, with some exceptions, the interpretation of events from the perspective of NIE, and the formation of policy positions from these perspectives seems limited. The reasons for this might be four-fold. First, so much has been focused upon the act of fishing and the resulting stock effects in a static and a dynamic context that comparatively little work (by economists) has gone into the study of the other institutions which evolved to function in this environment. Second, the static neoclassical model of the fisheries has seldom met any formal and frontal theoretical challenge by an NIE economist. Third, there appears to be an illusion that "creation" of property rights by the state, whatever that means, was the dominant policy recommendation of property rights theory, when in fact the recommendations were far more subtle than that. Fourth, a theory grounded in the Pigovian conception of the competent and benevolent state, developed and applied largely by public servants, can hardly escape arriving at the two policy conclusions of state-run privatization or state control [2].

This paper has two objectives. One objective is to discuss some of the recent applications of NIE to the fisheries. The other objective is to demonstrate how an NIE perspective can significantly change how one looks at data and interprets history taken from the fisheries, and what one considers to be relevant policy variables.

The next section begins with a brief description of NIE. The following section will expand upon the terms used in the first section. Next, applications of the NIE are discussed, in the context of fishery production and management. Finally, the paper offers an interpretive example of how an NIE perspective might change the way one views the issue of fisheries management.

## 2. WHAT IS NIE ?

NIE builds upon the work of classical institutionalists and extends the neoclassical rational choice paradigm of economic behaviour, by positing theories which explain the formation, change and demise of all *institutions*, including the market institution. It is an amalgamation of field observations and *a priori* hypothesis derivation and testing. Certain limitations of conventional economic theory, particularly assumptions pertaining to information and the ability of the individual rational choice model to forsee and explain collective behaviour, were addressed by these major branches of economics. The resulting theories are more susceptible to testing, yielding a rational choice model more applicable to a greater range of *in vivo* observations.

Since the field is "new", there is some divergence of opinion on basic theoretical issues. For example, Eggertsson (1991) advocates studying economic behaviour both of individuals and institutions from within the rational choice paradigm, but

1. It is interesting to note that the object of Coase's ridicule is a paper by Scott and Southey on the sole owner ; itself an important contribution to the neo-classical literature on the economic theory of the fisheries.
2. In the famous good road\bad road debate between Frank Knight and A. C. Pigou, for example, it almost seems as if they are arguing theoretical points from different institutional perspectives. One would think that to Pigou, the Crown ultimately owned the roads, was empowered to manage the roads, and therefore was obliged to do something about the problem of congestion. This reality of the British system makes it tricky even when Canadians swap economic theories of resource use with Americans.

using the theoretical extension of *transactions costs*. He differentiates institutional economic thought into New Institutionalist and Neo-institutionalist (which he calls NIE) factions. The difference between the two factions is that the New institutionalists, according to him, tend to reject the rational choice paradigm of the neo-classical tradition in favor of "bounded rationality" models. The Neo's retain the rational choice paradigm.

Explaining the mechanisms by which different institutions form and change is a strong focus of NIE literature. Ostrom (1990) takes a "field biologist" approach to deriving testable hypotheses, preferring to choose and analyse selected cases of commons management, principally from the fisheries, to demonstrate those attributes of small group (50 to 1500) dynamics which contribute to or detract from commons management. She also provides a history of the "Tragedy of the Commons" literature, and the two major policy solutions which have thus far fallen out of that literature : Privatization and state control. Ostrom casts these as various forms of the "Hardin Prisoner's Dilemma" game, and concludes that none necessarily guarantee Pareto superior moves from open access, essentially for the reasons described by the Public Choice and Property Rights theorists. Endogenously-derived rules are demonstrated to be potentially Pareto superior to either state control or privatization, under some well-defined conditions. Although there are examples of failures in commons management, there is significant empirical evidence to suggest that individuals and collectives are not *a priori* doomed to exploit their resources in a state of anarchy.

There are subtle theoretical disagreements within NIE concerning the costs of overcoming transactions barriers to get things done, and the role (and cost) of individual and collective innovations designed to dismantle the barriers. Ostrom still sees the rent dissipation of open access as a sign of inefficient allocation of resources. It is in fact inefficient, if there is an observable, endogenous mechanism which, if more artfully exploited, will render the open access condition undesirable to a rational human. Other authors arguing from Eggertsson's perspective seem to suggest that rent dissipation can certainly be a motivation to form contracts, but it cannot be a sign of inefficiency, without knowing more about the transactions cost environment, and the real opportunities to invent devices or rules that reduce those costs, or that slow the dissipation. Still, there are numerous points of agreement among NIE economists.

## 3. TERMS, CONCEPTS AND CONTEXTS

### *3.1 Institution*

An institution is an understanding between individuals concerning the way in which they interact in a specific activity. It is also characterized as a set of rules as well as a manner of enforcement. Both of these components can be defined and applied ranging from very informal agreements with no enforcement to highly rigorous and stylized rules. It seems that most researchers also concur that institutions are endogenously formed, arising out of the need by individuals as well as the collective to facilitate and coordinate social transactions given the cost environments which prevail. Thus institutions are rule structures which are created out of the desire to economically deal with *costs of transacting* [3]. Institutions evolve as the *transactions cost* environment changes, although lags in institutional adjustment are common, particularly in situations of rapid changes.

Since an institution is largely the result of efforts at dealing with *transactions costs*, the regime of open access (*res nullis ; constrained anarchy*) is an institution in which those involved might at least tacitly agree to no rules and no enforcement, because the costs of transacting are too high to consider other alternatives. In situations where conflict costs are low, this institution may be the source of significant amounts of surplus flow into an economy. The regime of *common property* management, under certain well-defined cost environments, has been demonstrated to be a highly effective institution for managing resource bases and is even the model used in modern corporate activity, as well as in subsistence economies (Bromley and Cernea, 1989 ; Acheson, 1975 ; Feeny et al 1990). It is also what is most often encountered in the fisheries, despite the language used by some economists. The *market* is an institution of high order, usually with high costs of creation and maintenance. Markets can exist even when transactions costs are positive. In the unlikely event that

3. It is important to reflect on a hind-sight analysis made by Coase on his most famous two papers, taken during an interview with Eggertson (1991) : "Transactions costs were used in one case to show that if they are not included in the analysis, the firm has no purpose, while in the other, I showed, as I thought, that if transactions costs were not introduced into the analysis, the law has no purpose."

*transactions costs* are zero, then markets exist for all things, and they will replace all other institutions motivated by economic interest, including the *firm* and *government*. However, firms and governments thrive, and non-market institutions abound. Therefore, to admit any institution besides a market into a theoretical analysis is tantamount to admitting existence of transactions costs, and by inference, imperfect information. The richness of economic theory becomes apparent not when we study the abstract firm embedded within perfectly defined markets (which, from an NIE perspective is a theoretical redundancy) but when one realizes that firms exist *because of* imperfect information. To an NIE economist, *government* and *law* are, at least *a priori*, economically motivated inventions which are an important first step toward reducing the cost environment sufficiently for other institutions to exist [4]. Aknowledging a transactions cost environment renders the neo-classical paradigm intellectually pertinent, but admitting the existence of this environment does away with the model's power to propose an *optimum optimorum* to guide toward, other than the general efficacy of enforceable contracts, where possible (Randall 1983). The NIE is particularly destructive to normative economics, which attempts the theoretical demonstration of the inherent inefficiency of certain institutions against the standard of perfect competition.

### *3.2 Information and Transactions Costs*

Given that imperfect information transmission exists in real economies, the economic problem of the extent and form of contracting becomes the primordial issue. High information and transactions costs (ITCs) can preclude the emergence of markets even among the most well-intentioned traders. In these cases, non-market institutions may take the place of markets, with their own specific "rules" of operation. These institutions take many forms, but generally reflect the circumstances in which they evolve. As pointed out in the literature, the institutions which do emerge are those which minimize transactions costs under a given state of nature, and as this state is modified, so are the institutions on which they are based. For example, the firm might be viewed as a command economy in miniature organized by a nexus of long-term contracts. It is characterized by the suspension of continuous pricing of outputs, and where inputs are managed by the entrepreneur (Eggertsson, 1991). Coase (1937) seems to view the size of the firm as a function of entrepreneurial capacity, but also the ITC environment in which the firm finds itself. We can imagine that ITCs can be so high that it is economically efficient for individuals and for society to opt for open access. These are the cases where individuals and collectives are not competent or willing, because of cost considerations, to solve the technical problem of innovating institutions which reduce ITCs. Fortunately, both individuals and governments appear to innovate constantly to reduce those barriers which make for high ITCs. These innovations extend corporeal vision, hearing, and memory by remarkable means. Thus, institutional formation, change and destruction is endogenous, evolving continuously with the changing cost environment.

A theme associated with transactions costs is incomplete and/or asymmetric information on how contracts are formed. Certain institutions of high precision in contracting such as markets for hours of labour cannot emerge because conditions of imperfect or asymmetric information prevail, and moral hazard as well as adverse selection problems must be dealt with. For example, the difficulty in monitoring workers may lead to a preference for a non-wage contract, such as the share system present in some fisheries (Nabli and Nugent, 1989). The absence of markets for insurance explains the emergence of non-wage contracts, as is also evidenced in share cropping arrangements in agriculture.

### *3.3 Property and Rights*

The reason why there is a desire to surmount barriers to transactions is to negotiate with others for the exchange of rights. Formally speaking, a right is a social sanction which allows the person to benefit by behaving in specified ways, even if it means damaging someone else. Property is not an object such as land but is rather a right or a group of rights to a benefit stream that is only as secure as the duty of all others to respect the conditions that protect that stream (Bromley and Cernea, 1989). Many rights, as well as the negotiations for them, occur in non-market contexts, again because of transactions costs. The absence of such rights might provoke negotiations to establish an institution which more clearly defines rights, while the presence of non-attenuated property rights can allow negotiation of the exchange of goods and services. For example, the lack of clearly defined rights to fishing grounds prohibits the exchange of fishing rights

4. Nozick (1973) concludes that individuals in a state of anarchy as defined by Locke will opt for an entity to hold the rights to the legitimate use of violence. Furthermore, such an entity would be viewed by all as a Pareto efficient move.

through a market. While in many cases this has led to overfishing, there are also numerous cases of the emergence of information networks which virtually prohibit outsiders from participating in the fishery (Wilson, 1990). Finally, non-attenuated rights act very much like those environmental barriers which provoke transactions costs. Environmental stress on the economic system can force institutional change, but so can a moral imperative. For example, public management might hold non-attenuated rights to preserve bio-diversity, based upon inter-generational equity or on moral grounds.

### *3.4 Collective action*

NIE bridges individual economic behaviour with collective behaviour by providing an explanation of economic motivations for the formation of collective institutions. This is done essentially by borrowing heavily from the Public Choice and Public Finance literature. There are many important areas in the study of collective action, but the most germane to fisheries seem to be Rent Seeking and Commons Managment.

The fisheries are examples of Common Pool Resources (CPRs), based upon a *resource system* providing a flow of *resource units* (Ostrom, 1990). The CPR is a resource system large enough to make contracting for exclusive individual rights costly, although not impossible. A CPR cannot be jointly used, and is *subtractible* in nature. An interesting example of the production and distribution of CPRs in the fishery is the participation of fishers in the restocking of marine resources. The historical existence of private transferrable property rights granted by the Crown to individuals (usually nobility) for the river sportfishery in Scotland is cited as a primary reason for the survival of Atlantic salmon in Scotland while the species is virtually extinct elsewhere (Johnston and Lent, 1981). However, in Québec, where government is more populist, the policies of putting in place local collectively-managed Zones d'exploitation controllées (ZECs) for salmon rivers in the 1980's has encountered resistance, mainly from rural populations with lower incomes (Wilson, et al 1991). Oregon and Alaska, on the other hand, have been experimenting with the private provision of salmon in a CPR context (Wilson, 1991). Each institutional organisation for the provision of salmon is clearly framed by governmental institutions with different underlying philosophies about how "public" a resource such as salmon should be, and thus who reaps the benefits.

Rent Seeking (RS) according to Buchanan (1980) occurs when entrepreneurs target on rents or opportunities for rents which have already been discovered and concentrated, usually by government, instead of innovating ways to deal with transactions costs for a profit. Surplus which is burnt up in competition for these rents is a pure loss to the economic system. D'nes (1985) has explored the implications of RS for the static open access theory of the fishery. Another potential application of RS theory to the fishery could be to study the behaviour of both foreign and domestic fishermen under the special provisions for public input within the Magnuson Fisheries Conservation and Management Act (MFCMA) of the U.S. Some fishery managers in the U.S. feel that the MFCMA was a tool created mainly for displacing foreign fishermen. However, it is less able to successfully manage domestic fisheries. This loss of management control is because factions of the domestic harvest sector, who had strong RS motivations for supporting the MFCMA, are now directing their RS energies at the Regional Fisheries Management Councils (FMCs), as well as through other political channels. However, others maintain that the FMCs are good institutional platforms for regional-based commons management, in part because of the RS motivation. These opposing hypotheses either point to a dysfunctional institution which should be abolished in favor of more precise contracting, or to a fundamentally healthy institution for the management of the commons.

## 4. ACTUAL AND POTENTIAL APPLICATIONS OF NIE TO FISHERIES

There have been a few persistent "NIE" authors who have written on the fisheries, and who have challenged some of the presumptions of the neo-classical model of the fisheries, practically from its inception. This is a list of some who have used NIE arguments. Finally, one potential application of great pertinence is presented ; the efficient management of fisheries.

### *4.1 Actual Applications*

Cheung (1970) clearly explains why rent dissipation in the standard theory of the fishery is an asserted and not a derived result, and then offers a derived result using an n-person oligopoly model. He also advances the idea that certain types

of contracts carrying enforceable exclusion clauses have a low chance of forming in the face of the environmental realities of the ocean fishery. This discussion breaks open the questions of the internal validity of the static fisheries model as an explanatory and as a policy device.

Bromley and Bishop, both jointly and severally ( Bromley, 1969 ; Arnold and Bromley, 1970 ; Bishop, 1973 ; Bromley and Bishop, 1976) challenge the conventional wisdom and the policy prescriptions deriving from the fisheries model, by rigorously examining the broader welfare-theoretic implications of policies made to render the fishery more "efficient" (limited licencing, in their case). They make a convincing case that the position taken by most fisheries economists of the time was not put into the MFCMA for good reason ; because the profession never addressed the pivotal public policy question "efficiency for whom ?" in a coherent manner. They conclude that Congress was perhaps wise in ignoring economists' recommendations for obligatory limited entry.

Acheson (1975) argues that the tragedy of the commons did not necessarily hold in the Maine lobster industry, because unofficial inshore fishing rights are enforced through community pressure as well as outright violence. Fishers have even gone so far as to apply self-imposed trap limits and closed seasons, which resulted in a higher catch per unit effort, larger lobster size and higher incomes for the fleet. This implicit privatization of the lobster resources has led to fewer problems of overexploitation in contrast with the other marine resources of New England. Acheson thus challenged the "tragedy of the commons" but called on fisheries managers to seriously consider existing social institutions in the fishery when designing management plans.
Wilson (1975) demonstrated that there was no "tragedy" in the commons, at least in a comparative analysis of earnings of lobstermen within perimeter defended areas having well-developed communications networks compared to fishermen not having these institutions in place. Another example of information networks established in the harvesting sector is the California harpoon swordfishery (Lent, 1978). This fishery is characterized by relatively high search costs, and information networks have emerged as cost-minimizing (and competition excluding) institutions. Similar environmental and cultural realities of multi-species fisheries leads Wilson (1983) to suggest the return to simple, endogenously derived rules of use.

Lent and Drouin (1989) investigate non-market institutions in the provision of inputs to the Québec cod fishery. The seasonality which characterizes this fishery, brought about in part by the lack of limited entry, has resulted in considerable excess capacity in the processing sector. As a result, each buyer faces substantial risks of not obtaining sufficient raw material to process at an economically efficient level. Given the lack of insurance markets for this sort of risk, processors provide services such as credit, bait, ice, moorage and employment of family members of the fishing fleet in order to secure their loyalty and their landings. While the lack of a market for insurance (due to moral hazard) may explain the presence of this implicit vertical integration, some explanation may also be found in information and transactions costs. Wilson (1990) explains the dissemination of information among fishing vessels based on the theory of collective action. Individuals are not able to collect sufficient information for successful fishing, and thus some forms of contractual arrangements must be made among fleet members. This brings up issues of exclusion, free-riders and problems in cooperative behaviour. Wilson suggests that a better understanding of the functioning of information networks in the fishery would improve the quality of public management.

### *4.2 Potential applications ; Efficient Regulation of a Fishery Re-considered*

Perhaps one of the more important applications of NIE to the fisheries is to re-examine what efficient regulation actually means. Ostrom provides some empirical studies of small group dynamics in an effort to examine why some succeeded in commons management, and why some failed. However, a skeptic might respond by saying that it is no surprise that she can produce success stories when the groups are small. The problem is to find the same behaviour with big groups; Are large groups doomed to perpetual anarchy? Answering this question is the subject of this section.

There have been researchers who, instead of using the fisheries model to derive policy statements, have described the condition of open access in a dynamic context. These efforts have been very interesting and worthwhile, since the result has been a greatly improved understanding of the dynamic behaviour of the open access environment. One can build upon this work by demonstrating how a NIE perspective can change the way one looks at management problems, the data, and the relevant policy variables for public management. Several studies are discussed in light of the potential applications of the NIE.

From an NIE perspective, the first noteworthy thing about these analyses is that they are ex-post explanatory presentations of existing economic[5]. The fact that data were already being collected in quantities sufficient for a researcher to subsequently model the fishery suggests that there was already substantial economic interest in the fishery, or at least there was enough interest to warrant the expense of generating information.

The second interesting thing about these studies is that they analyse fisheries, just before or between major structural changes, away from what might be called pure open access. For example, there was a global moratorium on the taking of Blue Whales in 1965. Although some might criticize the timing and effectiveness of this action, it is nevertheless true that political action was taken at the international level to avoid wiping out the Blue Whale. It is also interesting that the political act of moratorium seems like one of those "bangs" in a "bang-bang" control model, which has been defended elsewhere as an optimal control in the face of extinction (Spence, 1974). Now, after nearly 30 years of consciousness-raising, estimates of Blue Whales are now around 10,000, up from fewer than 5000 individuals in 1965 (Ozincki, 1992). One possible explanation is that political institutions, even very large ones, eventually tend to disrupt open access cycles. If this is so, what keeps them from being more "rational" more quickly, and what is the role of the economist in this context?

Wilen's (1976) dynamic analysis of the open access condition on the Pacific Fur Seal fishery ends in 1900, after which the fishery came under the control of a single firm. The approach to a dynamic equilibrium in open access was again disrupted. In this instance, it may well have been because the fleet became so small and centrally located that they were able to communicate with one another sufficiently well to form the Victoria Sealing Company in 1896. It appears that the disruption of this dynamic process in open access has an NIE explanation related to transactions costs. When enough fishermen left the fishery, it became organizationally feasible to consider other institutions besides open access. The chronology of the Pacific Halibut fleet (Orth et al 1980) suggests that in the late 1930's, similar attempts were made to organize that fleet during a time when stocks were down. To take another example, the first limited licencing program in the U.S. was enacted into law in Alaska in 1973. The enabling legislation came in the wake of some of the worst stock levels of salmon in recorded history. Conrad (1986) suggests that the MFCMA dealt with some but not all dimensions of open access. The legal framework of MFCMA "boxed up" the open access solution, but after a period of adjustment, domestic fishermen could be seen drifting towards a new dynamic equilibrium in open access. So the idea of simple and incremental solutions to problems brought on by a persistent open access phenomenon is visible within several well-known studies.

Two other NIE interpretations might fall from these observations. Technological change in public management tools follows the same laws as does technological change in the private sector. Change is motivated by need as well as the stock of knowledge necessary for application. Inventions contribute to the stock of knowledge, but may not be directly applicable as innovations. This stock is independent of the discoveries of any one person. As need coincides with stocks of knowledge, innovations or practical applications of inventions occur. Part of the frustration that economists may feel as public managers could be related to the timing problems associated with introducing innovations, as well as the act of innovating itself. Suggestions about how institutions could be cost effectively changed build a store of inventions which at the appropriate time can be applied as innovations. However, the innovation or application of an invention is related to the competence of the public inventors and innovators, as well as the timing and institutional context in which they find themselves. Many inventions are clearly too costly to effect, because other necessary infrastructure is not yet in place to accomodate the innovation. The other NIE-type observation is that open access conditions are nested and chronic. They are "boxed up" by the evolution of institutions, but they never go away. Talk of "solving" the open access problem in general is pointless.

Conrad and Bjorndal (1987) provide a base from which one might make further interpretations with an NIE perspective. Their analysis demonstrates the open access condition with data taken from the North Sea herring fishery, with the well-known spiral tendancy towards a dynamic open access equilibrium. However, as with the Blue Whale, the structural interruption of the dynamic cycling is a moratorium on fishing. They suggest that patching behaviour of herring schools makes for a non-increasing industry cost structure, which makes it easy for that industry to wipe out the stock. Because they publish their raw data, it is possible to exploit and perhaps take other interpretations away from their work. These interpretations suggest other possibilities which might be useful to managers willing to forgo attempts at "solving" the open access problem.

5. Some might argue that there is nothing "striking" about the fact that ex-post explanatory presentations of existing economic conditions can or had been done. We would agree, were it not for the fact that information is costly, and the hows and whys of its acquisition and disappearance figure heavily into management decisions. The question of what to record and maintain as history (and therefore what information will survive to be re-analysed) as well as who will have access to this information is far from a trivial topic.

The work of Bjorndal and Conrad (1985 and 1987) (B&C) was re-analysed using Quattro Pro version 4.0. The objective was to look at the sensitivity of their parameters on the dynamics of the fishery, as well as to demonstrate how an NIE orientation might change how one model the dynamics of endogenously derived institutional change. The first step was to verify the dynamics of the model. There are no surprises, except that the model was extremely sensitive to changes in certain parameters.

Part of the verification included positing what we believe to be reasonable relations describing ex-vessel price and average per boat cost. Lagged relations for these two important variables were estimated. The results of these estimates performed on Statgraphics 2.6 are presented in Table 1. It is noteworthy that we may have uncovered some evidence of a negative relationship between average costs and stock levels, although there have been some cogent arguments in the literature why we would not expect this result in the North Sea Herring fishery (Bjorndal and Salvenes, 1993). Perhaps more robust is the negative relation between ex-vessel prices for herring and landings.

14 observations fitted, forecast(s) computed for 0 missing val. of dep. var.

B&C's estimate of the maximum price per ton of herring (2000NoK) is used. Another change which might bear upon the comparative interpretation is that there is always at least one vessel in the fishery in this formulation. This does not seem to be an unreasonable assumption, given that the stocks of many fisheries are still monitored by direct sampling. Estimated instead of observed values of Pt and Ct were used, which filters out the stochastic problem (which can be important) and makes the trajectories look smooth. Finally, this simulation does not correct for measurement errors in discrete time. This might explain the divergence between the observed and simulated dynamic paths. The simulation is to the year 2003. However, our objective is not to make predictions but to observe the sensitivity of the open access model. One surprising feature of our simulations is that the stock does not become extinct over the range observed, neither when using a mix of real and simulated data nor when using simulated data, and using the parameters of B&C (Figure 1a).

It is often argued that simple rules such as global quotas or gear restrictions, and tactics like maintaining barriers to information transfer are suboptimal, compared to more refined management methods. To some NIE economists at least, sub-optimality is a moot point, compared to the problem of extinction and the tractability of centralized plans from an ITC standpoint. Within the dynamics of large groups, simple rules may be all that can be assimilated and agreed upon, and without a clear notion of ITCs, one simply does not know how "sub-optimal" these rules are. However, because of the positivist approaches of many dynamic analyses, it may be possible to see why fisheries managers and fishermen in large groups have tended to focus on simplicity and incrementalism, instead of more fundamental solutions invented by economists. First, an attempt is made to show why this happens. Simple rules tend to focus directly or indirectly on the productivity of factors used in fishing. In real situations, these controls are diverse, but are generally divided into Time, Area, and Gear restrictions. Gear restrictions are the most obvious example of "regulated inefficiency". In the paper by B&C, they estimated a parameter b, which is the elasticity of production for capital (Kt). It is this parameter which might be affected by such simple rules.

In a world of perfect and symmetrical information, markets are the dominant institution, and inframarginal profits are dissipated immediately for all factors of production, including (homogeneous) entrepreneurial capacity. In such a world, it is obviously irrelevant how much faster rents might be dissipated after the discovery of an unowned resource. But in the real world open access fishery, proprietary knowledge of information may well be the only effective barrier to rent dissipation. This may explain why fishermen try to affect entry and exit by maintaining information asymmetries; because it is an important rent preserving strategy in a commons management framework. The parameter n (the responsiveness of Kt for a dollar of profit), also estimated by B&C, would be affected by these individual or public policies.

Finally, the notion of the endogenous nature of institutional evolution in the face of persistent open access is a new concept which owes its existence to the NIE. Adoption of that theoretical point of view might suggest that the existence of open access is of limited importance, but the control of its effects during institutional evolution is crucial. The role of the manager changes from one of innovator and implementer of rules to one of ITC manager, where the objective is to encourage the disruption of the open access cycling, and to constrain it to a less damaging form. We will demonstrate the importance of ITC management with the help of some model extensions.

### *4.3 Changes in b*

Changing b, the elasticity of production for capital is the modelling analogue of gear and other technical restrictions on the fishing industry. Although regarded as relatively primitive and inefficient, the effects on the fishery of relatively minor

changes in its value can be very pronounced. The original trajectory using B&C's estimates is depicted in Figure 1a. If the value of b is increased up to one standard deviation from the mean value estimated by B&C (from 1.3556 to 1.4383), the trajectory "unrolls" to a point where extinction is assured (Figure 1b). When b is reduced by one standard deviation below the mean value (1.2729 from 1.3556), the spiral tightens toward a dynamic equilibrium with a stable positive capital and fish stock (Figure 1c). This is an example of so-called "regulated inefficiency" in an industry, but it is readily understandable why managers might resort to it. Relatively simple and low cost to put into place and to control, the effects are striking. Such a measure can avoid the large erratic spirals which eventually bump into either the capital stock or the fish stock axis. If one cannot induce a workable sea-tenure system tied to the resource base on the down-side of the first or second cycle, (like what happened "by mistake" in the Alaska salmon fishery) the least that should be done is to dampen the oscillations by negotiating rights to impose gear restrictions. If the objective is to encourage the emergence of new institutions, one might ask if gear restrictions encourage change. If alternative attainable institutions exist in a given ITC environment, we may see change motivated by comparing rents in open access versus other regimes. However, with stable capital and stock levels, ITCs have to fall in order to provoke an endogenous change. The reason for wanting the fishery to experience "biologically safe" open access is to entice the system to disrupt itself. If public management systems are geared to trying to reduce the ITCs of collective rule formation, hard simple rules can provoke more refined institutions.

### *4.4 Changes in n*

B&C(1985) estimate an adjustment function related to the profitability of the fleet interpreted as "boat dollars"; the amount of capital attracted into (out of) the fishery for an increase (decrease) of one dollar in profits.

Learning curves and start-up costs in fisheries like high-seas herring can be steep. On the other hand, B&C estimate that alternative fisheries and opportunity costs also affect capital dynamics. Some of their best estimates of capital dynamics (1985, Table 5, LIII.3) include parameter estimates for the opportunity cost of capital. In these cases, assuming positive effects on capital growth, n1 = 0.2390. When the point estimates contributing to the outflow of capital are added, then n2 = -0.1644. There is no reason to suppose that rates of inflow incited by an additional dollar of profit will equal rates of outflow for one dollar of loss, and in fact B&C note this as a possibility. This reasoning is used in order to modify the capital ajustment equation such that n1 = a*n2, a 0. In Figure 1a, the trajectory corresponds to the situation where a =1, and the parameters are set to those used in B&C's 1987 paper. Diminishing a by only 13 % (to .87) suggests that capital flows more easily into the fishery than it flows out, and thus leads to the extinction of the stock (Figure 1d). Increasing a by 13

would suggest that the flow of capital is relatively slower to respond to profits than it is to respond to losses. This tightens the trajectory spiral rapidly to a positive fish and capital stock level (Figure 1e). Information asymmetries as well as other incentives aimed at changing the cost of entry andør exit can have a profound effect upon the fisheries. For example, public efforts at improving profitability of open access fisheries can lead to management nightmares in one case, while in another case it would be considered useful. The public knowledge that opportunity costs are high in a certain fishery can affect the rate of exit. Informational barriers imposed by fishermen on profitability and location of fish may play an important role in slowing the rate of entry. Information, in effect, is the ultimate control variable in the NIE framework. Innovations in information management which affect entry and exit can ultimately lead to stable resource use institutions.

### *4.5 Triggering institution formation*

Although much work has been done on examining those parts of our economy which are related purely to the management of transactions costs, quantitative descriptions of the ITC environment of the fishery seem to be absent. However, we suggest that both timing and management innovations appropriate to the transactions cost environment play a large role in institutional evolution. To show this, we take a very simple world in which there is open access, as described by B&C(1987). Another regime was posited in which it was assumed that fishermen could contract with a management agency to impose a global quota at a (hypothetical) ITC cost of 20*(#vessels)1.2 per vessel, based upon the assumption that it costs more per participant to agree to strike a deal with greater numbers of individuals. We wish to stress that these are hypothetical ITC functions, because no real ones exist at present. However, it would seem that the measurement of ITCs and their effect upon the behaviour of fishermen would be an important line of applied research.

It is assumed that the management agency can and will enforce a global quota of MSY. In fact, any time the stock falls below K/2, where K is carrying capacity, the fishery closes except for one vessel which monitors the stock (this is done for computational convenience, but it can also reflect some practical realities of management; information is needed on the stocks). Note also that no one is excluded from the fishery, but the global quota is respected rigorously. Further, the decision to have a global quota and when it is to be put into place was made by the fishermen themselves, and is a function of the comparative net benefits of each regime for the representative boat owner, assuming a homogeneous fleet. The actual modelling exercise simply says that when the average fisherman, with a knowledge of the aggregate harvest and stock effects on his future individual earnings, encountered multiple periods where individual net benefits with global quotas exceed those in open access, he or she would be willing to form a contract with the agency to put the new regime in place, even with positive transactions costs. Homogeneity of the fleet assures a relatively clean collective decision, again for purposes of exposition. Another feature of this analysis is that once an institutional change is made, the management agency will not let the fishermen abrogate the contract. This is realistic because public rule formation tends to be somewhat "sticky". Once a system goes through the trouble to form a collective contract, its abrogation is usually difficult to accomplish. The results are in Figure 2. The industry rounds the first corner and the number of fishermen begin to decline. The declining stock has taken its toll on the profitability of each boat. The institutional "innovation" is present and the (hypothetical) ITC environment is favourable, so a change is made in "1971". Notice also that the result appears to be a stable limit cycle similar to pulse fishing, but this is only if public and private managers do nothing to encourage further institutional innovations. One can easily imagine continued refinements which further change the trajectory, perhaps even provoking a dynamic equilibrium. The point of this discussion is that such behaviour, which exists in reality, is a very encouraging sign. Despite the continued existence of open access, rational economic choices can be and are still being made. The job of an economist, from the NIE perspective, is to help make sure that the transactions cost and informational environments are such that rational choices can continue to be made.

## 5. CONCLUSIONS

NIE is a cogent extension of the rational choice model of economic behaviour which offers much in terms of how to model and test observations on economic behaviour. The emphasis in NIE fisheries management is oriented towards managing ITCs so that the industry will contribute substantively to the evolution of collective institutions. Economists can help by being ready to work on the practicalities of making it easy to form contracts. This work can include proposing institutional changes, but these proposals need to be geared to an ITC environment. Timing is also important.

The decreasing costs of information accumulation and management might change public management by allowing agencies the option of looking at efficient rule formation or institution building which is tied to catching the industry at the right time with the right innovation. As such institution-building continues to cut away at the never-ending open access "problem", we may see more rapid convergence to "rational" resource use, but the process will essentially be the same. The incremental formation of rules will be subject to informational constraints. Agencies have a role in this process, but it might be more to minimize ecological disasters having inter-generational economic impacts while the economic system grapples with the shorter term resource problem. Government also can innovate ways to reduce transactions costs. Simple rules work ; moratoriums, seasons, gear restrictions, and global quotas. Providing a forum for the measured exchange of management related information seems to be important. In this sense, the "Regional Management Councils" of the United States are potentially very potent institutions. This economic point of view is summed up by Coase :

> "....there can be found in fisheries errors so gross that we can have little doubt that a certain kind of change would be beneficial. Perhaps therefore what we should do is to concentrate on these cases (so far as our policy recommendations are concerned) and leave other problems alone. And, perhaps, if we reiterate these recommendations over a long enough period, one day the political forces will be such that, probably for reasons which would not commend themselves to us, our proposals will be adopted because they are there."(Coase, 1970)

In a well-functionnary society, those "political forces" are motivated by individuals ready for a change. This willingness to change will make certain proposals *feasible*, where before they were not. While economists should not always expect to have an audience, there is still some use for them as inventors of possible rules and managers of ITCs. However, their usefulness is in direct proportion to how well economic recommendations resonate with the transactions cost and institutional environments of the real world.

# Cooperative Fishing Arrangements between Coastal Countries and Distant Water Fleets

**Lewis E. Queirolo [a] and Richard S. Johnston[b] ***

ABSTRACT

*While extended jurisdiction has characterized most fisheries for the past 15 years, nations continue to look for their comparative advantage positions in that sector. In so doing, they sample from a variety of production and trade arrangements. Consequently, numerous arrangements may co-exist, perhaps for extended periods. An important dimension of such arrangements is their duration.*

*Consider, for example, a coastal state that seeks to uncover a latent comparative advantage in fishing and, thus, forms a cooperative fishing arrangement with a foreign partner through which virtually all fishing decisions are made by that partner under a long term contractual arrangement. The planned life of that arrangement will influence the extent to which the potential yield of the resource is husbanded by the foreign partner. This, in turn, will determine the long term success with which the coastal country develops its comparative advantage in fishing.*

*In analyzing the nature and consequences of such cooperative arrangements, it is important to distinguish between the effects on resource use and the way in which the benefits are divided between the partners. An important dimension of the latter is the role of information on biological and market conditions. Such information is often asymmetrically held by partners. As a consequence, the terms of cooperative fishing contracts may be designed to address equity issues. These are different from, but not necessarily independent of, efficiency issues. This is particularly true when partners discount the future at different rates. It is important for the analyst to be aware of these efficiency and equity issues and how they relate to each other.*

* The authors are grateful to Grant G. Thompson and Russell F. Kappenman for both helpful insights and technical assistance in preparation of this paper. Discussions with James D. Hastie, David A. Colpo, and Gilbert Sylvia have also been valuable.

Partial support for the research reported here has been provided by the Cooperative State Research Service, U.S. Department of Agriculture (Agreement No. 92-34276-7140) and by the Alaska Fisheries Science Center, Alaska Region, National Marine Fisheries Service.

The findings in this paper are solely those of the authors and do not necessarily reflect the opinions of the National Marine Fisheries Service, NOAA, or the U.S. Department of Commerce.

*On the other hand, it is also important to distinguish between the terms of agreements between partners operating in isolation and those that result when there are many potential partners. Competitive conditions on both sides of the market for access to resources may generate incentives to signal resource values by competing bidders and, in the process, reduce the magnitude of the asymmetric information problem. Competition, then, may address the efficiency issue. Equity considerations may remain, however, and could be large enough to overwhelm efficiency concerns. Indeed, this may explain why actual contractual arrangements in the world's fisheries diverge from those predicted by the competitive model.*

## 1. INTRODUCTION

The world's oceans have been regarded through time as the common heritage of all mankind, held in trust for the collective good. When demands upon the oceans were relatively few, this noble philosophy was probably not unreasonable [1]. But the burgeoning of human populations and the accelerated growth of technology have conspired, in the latter decades of the twentieth century, to make the concept of a "common property interest in the oceans" functionally obsolete. High speed vessels and aircraft, satellite communication and observation, radar and radio, among others, have extended our political and economic reach beyond the coastal horizon.

Technology has made possible, for the first time, exercise of effective "private property rights" over the, heretofore, remote and often fugitive resources of the extended continental shelf and high seas. Population pressure, leading to increasing consumptive demands, has in many cases made these changes imperative.

In response, many coastal nations have unilaterally extended economic jurisdiction over adjacent waters, traditionally regarded as "open ocean." While petroleum exploration, minerals mining, etc., have been a consideration in extended jurisdiction, living marine resources, and particularly economically valuable fish stocks, have been the principal focus.

One consequence of the nearly universal extension of fisheries jurisdiction (EFJ), which has taken place over roughly the last fifteen years, has been the acquisition by coastal nations of virtually exclusive control of the fishery resources off their shores. In most circumstances, this has resulted in an enormous, and relatively abrupt, international redistribution of wealth.

## 2. COOPERATIVE FISHING ARRANGEMENTS AND GAINS FROM TRADE

Where the fleets of "traditional" distant water fishing nations once operated with complete autonomy, exploiting the fishery resources of the world's continental shelves, they have now, in large part, been displaced. Only when distant water operators have been able to demonstrate to newly endowed coastal states that joint benefits would accrue by their presence have cooperative fishing arrangements emerged. Munro (1985) has demonstrated the potential gains from trade that accompany such arrangements.

In examining the development and evolution of these cooperative fishing arrangements, research has been directed primarily at the economics of bilateral and multilateral agreements, or on the short run behavior of the respective cooperating partners (see, for example, Clarke and Munro ; Kaczynski ; Kerr and Sharp ; Johnston and Wilson ; Anderson and Sutinen). Little attention has been paid to the reaction of other, potentially competing, coastal and distant water nations. That is, the bulk of the economic literature on this topic centers on the potential short term benefits to the newly endowed coastal state, which may accrue from entering into a cooperative fishing agreement with a foreign distant water operator. These benefits may include technology transference, access to new markets, realization of gains in domestic consumer and producer surpluses, and extraction of resource rents from the contracting distant water nation.

But this approach stops short of examining the intermediate and long run implication of joint-venture arrangements for the coastal nation, its distant water partner(s), and the fishery resource itself. As each party acquires experience and

1. In point of fact, because of the limitations of knowledge and technology, this perspective was likely as much a reflection of pragmatic reality as of altruistic ethos.

information from the cooperative arrangement [2], short run adjustments are made, both by the parties themselves and by the broader community of coastal nations and distant water fleets. These latter groups represent potential competitors, whether supplying "access" or "expertise", and may influence the form and stability of future cooperative arrangements. What emerges, we have argued (Queirolo and Johnston, 1988), is a market for access, created precisely because of the widespread movement away from "common property" rules of exploitation of the resource, towards "private property" rights.

In the present paper we extend our earlier analysis, in part, to embrace arguments advanced by Clarke and Munro (1980) under which the coastal nation and the distant water fleet are assumed to have different discount rates. They argue that, under this circumstance, the coastal nation will be unable to design an incentive scheme that induces the distant water fleet to harvest the resource as if the coastal nation's discount rate prevailed. Theirs is an imaginative use of principal-agent theory to demonstrate the existence of an "incentive gap" and the resulting inappropriate (from one partner's perspective) exploitation of the resource.

We propose an alternative perspective : namely, that the presence of competing buyers and sellers of access eliminates Pareto relevant externalities and, in so doing, removes the need to design complex contractual, monitoring, and policing arrangements. We do not suggest that the market for access is perfectly competitive. Rather, by considering what the "access market" would look like if it were, analysts can better understand actual arrangements by focusing on the nature of and the reasons for deviation from the competitive model. The arguments presented here are preliminary in nature. Nonetheless, we hope they stimulate discussion of an important issue in global fishery management.

## 3. COOPERATIVE FISHING ARRANGEMENTS AND THE PRINCIPAL-AGENT FRAMEWORK

Perfect competition is characterized not only by large numbers of buyers and sellers, but also by relatively accessible information. In the case of cooperative fishing arrangements (cfa), however, it is significant that the "accessible information" condition may be violated. Indeed, it is highly likely that, when assessing the relative positions of two participants in a cfa, information will be asymmetrically held. For example, most distant water fleets come from countries with relatively long histories of involvement in industrialized fishing and, in many cases, with established markets for fisheries products. Thus, decision-makers within these fleets will hold more information on the fishing process (especially large scale fishing), on processing and product technology, and on market conditions. They may, in fact, know more about the condition of the resource and its population dynamics, than the host country. In addition, since their fishing activity takes place away from the view of the coastal state, information on catch rates, discards, and other variables crucial to economic decisions will be held disproportionately (if not exclusively) by one side - the distant water fleet.

It is this feature of many two-party arrangements that has led Clarke and Munro to view the issue within the context of the "principal-agent" framework (1987, 1990). In their work, the coastal nation - the owner of the fishery resource - is the "principal" who grant the "agent" - the distant water fleet operator - permission to participate in the exploitation of the resource. The authors demonstrate that a mix of fees and taxes may cause the agent to act in a fashion that is consistent with the principal's best interests, although the situation is muddied when the two parties discount the future differently. It may be helpful to review some of the key findings of their work, before proceeding further with the presentation of our own.

First the Clarke-Munro (hereafter,CM) analysis, in which fee fishing is the specific cooperative fishing arrangement analyzed [3], is motivated by the inability of the coastal nation to dictate effort - and, therefore, harvest - levels to the distant water fleet. CM assume, however, that all cost, production, and market relationships are known with certainty by both partners. The work, then, abstracts from some features of "real world" cfas. Even under these conditions, the authors demonstrate that, when the coastal nation and the distant water fleet value the future differently, there will be a difference between them regarding the optimal level of resource exploitation and they are unable to devise a tax-fee scheme that closes the incentive gap. This appears to imply that, contrary to one of the basic premises of both this paper and our

2. Information may not accrue to the two parties symmetrically, however. Because information may be employed to the advantage of one party and at the expense of the other, in such a situation, the asymmetry of information is an issue we consider in further detail in this paper.
3. Although they argue that their approach is appropriate for other cfas.

earlier work, the effort level that maximizes social benefits is not independent of how benefits are distributed between the partners. We suggest, however, that this is the case only in the absence of competition, i.e., the finding follows from examining the issue as one between a single coastal country and a single distant water fleet.

Second, the principal-agent analysis reveals that, when both parties discount the future at the same rate, imposition by the coastal state of either a profit tax or a lump sum tax on the distant water partner could lead to the same result as would direct control of effort and, therefore, harvest. That is, there exist policies that would induce the distant water fleet to use the resource in a "socially optimum" fashion, from either country's perspective, irrespective of which nation owned it. All that is necessary is for the distant water partner to receive a return over the course of the harvest program that is just enough to induce it to participate in the fishery. This minimum return, "... may be determined by market forces or by negotiation" (p.6). CM reject these options, however, as being politically infeasible. For our purposes, it is sufficient that such policies exist.

Third, when future income is discounted more heavily by the distant water fleet than by the coastal country, the above finding does not hold. While there does exist a payment that would induce the fleet to participate in the fishery, that payment would have to occur entirely, "... at the first instant of the exploitation program. The reason is transparent : any return received by the agent after that first instant will be worth more to the principal than to the agent" (p. 7) [4]. The difficulty, however, is that "... if the agent receives its entire share of the benefits from the fishery in the first instant, it has no reason to continue on in the fishery, unless compelled to do so,... an obvious moral hazard problem" (p. 7). It is this result that leads CM to consider a mix of fees and taxes as the way to address the problem. As indicated above, however, they are unable to find a mix that closes the incentive gap between the coastal country and the distant water fleet. It is our position, outlined below, that "competition" also addresses the issue.

Finally, CM points to the possibility that a coastal nation may value future income less than does its distant water partner. This could be the situation if, "... the principal is a developing country and... the agent is a capital rich developed country" (p. 29). As CM point out, the coastal country would "... make the greatest economic gain by simply selling out the resource at the commencement of the program" (ibid). This is unlikely to be politically feasible, however, and thus the authors conclude that the income-maximizing solution for the coastal country is to devise a taxation policy that, it turns out, is more conservationist, i.e., maintains a higher sustainable stock level, than would be the case if the coastal country controlled the fishing effort. CM confine their discussion of this point to a footnote. Yet it may be among their most valuable insights. Indeed, it is this phenomenon that leads Kaczynski to advocate use of joint-ventures by developing coastal nations. In a recent paper, for example, Kaczynski (1991) argues that the fishing activity of a developing country's fleet would, "... without timely government intervention and proper conservation measures,... lead to the depletion of the coastal fishery resource and destruction of artisanal fisheries" (p. 12). He sees joint-ventures with developed countries as one way to avoid this consequence.

The CM analysis offers important insights into the problems the coastal resource owner confronts in dealing with a distant water fishing partner, and helps to place certain conflicts in perspective. For example, Chile's early dissatisfaction with some joint-ventures it had with Japan may reflect differences in information about market conditions between the two partners. Peru recently rescinded fishing licenses it had issued under a three year contract to twenty factory trawlers from the former Soviet Union because "...Peru says that the Soviets have not met the terms of the contract" (Fishing News International, June, 1991).

The world is, however, witnessing a movement towards increased opportunities for cooperative fishing arrangements. Thus, we propose expanding the CM analysis to examine the likely consequences of active competition among buyers and sellers of resource access. We extend the four findings summarized above to the case of access competition.

## 4. MANY PRINCIPALS AND MANY AGENTS

We begin by considering the first, third, and fourth of the CM points summarized above : (1) different assessments of future earnings lead to an incentive gap ; (2) only lump sum payments will work ; and (3) some coastal countries may have higher rates of time preference than do their distant water partners.

4. In other words, it is only at the initial time period when the present value of the payment is the same for both principal and agent. Any one payment in a stream of payments consistent with that present value will, by itself, be discounted differently by the two partners.

The CM analysis is motivated by the assumption that coastal fleets are unable to dictate the behavior of distant water partners. In their model, the coastal nation is assumed to know what would be the optimum effort levels from the perspective of both partners. Under these circumstances, the coastal nation will be motivated to provide the opportunity to competing distant water fleets to become long-term cfa partners. If a particular coastal nation is the only one offering fishing opportunities to distant water fleets, and if there are many such fleets, a solution would be to auction fishing rights - with indefinite tenure - to the highest bidder. If all competing fleets are identical except for their social rate of time preference, and if those rates are higher than that of the coastal country, the successful bidder would be that fleet with the lowest rate ; i.e., the one closest to that of the coastal nation [5]. Where the coastal nation values future earnings at a lower rate than do the distant water competitors, accepting the highest bid means the Kaczynski result emerges, yielding more resource conservation than would otherwise occur.

Next, extend the model to include many competing coastal countries. Now each distant water fishing nation will seek to select fishing arrangements that maximize the present value of the payments it receives from the cfa, over time. In the bidding process of the above paragraph, this amounts to offering low bids. Suppose the social rates of time preference range from the very high to the very low, on both sides of the market. As a consequence of this bidding competition for resource use and access, competitive equilibrium will bring together those partners at the margin with equal valuations of future earnings. In the limit, of course, the competitive process may bring together distant water operators who share the same high rate of social time preference as the developing coastal country. In this situation, the "calming" influence provided by the presence of a developed nation's distant water fleet on the rate of fishery exploitation, anticipated by Kaczynski, will not emerge. In fact, prospects for overfishing of its newly acquired resource, by the developing coastal country, will actually be enhanced through such a joint-venture arrangement. This is, nonetheless, entirely consistent with our expectations concerning the influence of the duration of access.

Next, consider the political feasibility question. While lump sum payments may be politically unacceptable as between two isolated partners, competitive conditions may force their acceptance. Thus, we take issue with the CM observation that the case in which there are many prospective partners is "... much less interesting" than the case where "... fleets do not compete with one another" (Clarke and Munro, 1985, p.8 and fn.1). Their conclusion follows from their implicit assumption that the competition is only for access during the current period, meaning that, "(T)he foreign exploiters... have no 'stake' in the resource as individuals" (ibid. fn.9).

But we see no reason to suppose that the competition will not be for long term contractual arrangements of the kind CM explore in their principal-agent analysis and that we use here. There exist numerous examples of foreign ownership of resource access, even in the fishery. In many cases, it is to the economic advantage of the foreign owner to hire domestic labor, capital, processing and marketing services, etc. For example, U.S. maritime law permits up to 49 % foreign ownership of fishing vessels operating in its EEZ. In 1991, of the total U.S. catcher/processor capacity operating in the North Pacific and Bering Sea groundfish fisheries, foreign ownership was estimated to be on the order of 30 %. Similarly, in the same year, an estimated 80 % of the total Alaska shore based groundfish processing capacity, operating in the U.S. Bering Sea pollock and Pacific cod fisheries, was owned and operated by Japanese fishing companies. Furthermore, contracts that guarantee long-term access to international markets (those of the distant water nation) could be highly popular features of a contract in a coastal country that depends heavily on trade.

We recognize that this extension of the model takes us out of the principal-agent framework. Once the distant water fleet acquires fishing rights over an indefinite [6] tenure, the coastal nation would no longer have a monitoring problem and the asymmetric information feature disappears. Note that fishing rights, granted with indefinite tenure, are not the same as resource ownership, since only the fishing activity is at stake. It is more appropriate to think of such rights as having many of the attributes of transferable fishing quotas that are made available to non-citizens.

CM point out that, when the two partners discount future earnings at the same rate, the question of how payment is made is not an issue. We have addressed this topic above in the context of the competitive model. But our response really begs the question : why do the partners differ in how they value future earnings ? There are many explanations. We suspect that one reason it is commonly believed that distant water fleets discount future earnings heavily is that they have been

5. Following the CM argument, this fee would have to be a lump sum payment, because future payments would be valued differently by the two partners. However, if the successful bidder and the coastal country had identical rates of time preference, the method of payment would be irrelevant.

6. "Indefinite" is intended to pertain to provision of an extended duration of access and not to the issue of risk and uncertainty. These latter considerations are beyond the scope of the present paper, but will be treated in a subsequent paper.

observed harvesting at what appears to be highly exploitive, non-sustainable rates. We suggest that another possible explanation for this behavior may lie more in the tenure of the contract under which they fish than in their rates of time preference.

## 5. LONG RUN EQUILIBRIUM : RESOURCE USE VS INCOME ALLOCATION

Would one expect the market for access to generate a long run equilibrium solution analogous to that of the perfectly competitive model of economic theory ? Probably not, but that is not the salient issue. Rather, we suggest that, in the presence of EFJ conditions, one would expect the forces behind the neoclassical model of perfect competition to prevail. If, 1) access rights were negotiable over time, perhaps, for example, auctioned off to the highest bidder ; 2) transactions costs were minimal ; and 3) there were numerous buyers (distant water fleets and some fleets from adjacent coastal countries) and sellers (coastal nations), competitive efficiency should emerge and sustain, even in the face of changing economic conditions. That is, we would expect to see the rents dissipating "race-for-fish" on the fishing grounds, associated with open access conditions, replaced by competition at the negotiating table, or in the EFJ access marketplace ; a clear step towards economic "rationalization" of the fishery. If our argument is correct, this means discussion can focus on the characteristics of that process and on the conditions that might limit its applicability.

First, however, we wish to reiterate a point we made in our 1988 paper. It is important to distinguish between "resource use" and the "distribution of income" generated by that use. There is debate within the fishery management community, as well as the economics profession, over the need for and extent of enforcement and monitoring under EFJ cooperative arrangements to ensure that the fishery resources of the coastal country are efficiently managed by the contracted distant water operator. Consider the following hypothetical case. Assume, for the sake of argument, that the contracting distant water fleet was given sole access, for an indefinite period, to the coastal nation's fishery resource. In essence, this is equivalent to transference of "quasi-property interest" in the resource from the coastal nation to the distant water fleet. Assume further that the two partners discount the future at the same rate. The distant water fleet would, in this situation and under competition, have an economic incentive to harvest at the *same* rate as would the coastal nation, assuming the latter was "hiring" the physical capacity to fish.

This congruence of exploitation rates will emerge under a variety of contractual arrangements, e.g., a division of rents, lump sum payments (Cheung ; Clarke and Munro). Therefore in this situation, the only enforcement required would be by the distant water fleet, monitoring the performance of its own fishermen (i.e., self-policing). Of course, both parties would have an incentive to guard against potential third-party interlopers, to precluding a return to pre-EFJ "open access" exploitation patterns.

Under these idealized conditions, the distant water operator would, nonetheless, have an incentive to "cheat". But the incentive would not extend to "mismanagement" of the resource. Rather, they would seek to retain as much of the earnings (including resource rents) as possible. That is, the cheating would involve revenue distribution, not resource management (overfishing) considerations.

Among the most important characteristics of the arrangement which produces this equilibrium result is the assumption of "indefinite access" to the resource. Because of the temporary conference of access (essentially transference of quasi-property interest in the resource), consideration of the implications of "contract duration" becomes relevant to an understanding of the nature and stability of the cooperative joint-venture arrangement under EFJ.

Only when the contractual arrangement is of sufficient duration to impart an effective "property interest" in the resource, will the distant water fleet find its optimal rate of exploitation to be equal to that of the coastal nation. Absent such assurance of access, the "property interest" of the contracting fleet is so reduced that it will always seek to accelerate the harvest to the point of biological overfishing.

In practice, even with intensive monitoring and restrictive enforcement, the nearer the potential termination of the assured access, the greater the incentive to abandon cost minimizing and conservation maximizing practices, in favor of accelerate extraction of the target species. The combined costs of the necessary monitoring and enforcement programs, the inefficient use of productive inputs, and waste of fishery resources under these circumstances, results in the dissipation the potential rents (both short and long term) which could have been realized from a stable, equilibrium solution.

In effect, provision of short term access, with the probability of imminent exclusion, results in behavior, on the part of the contracted fleet, which approximates that of open access. That is, because there is no long term "property interest" in stewarding the resource on the part of the distant water harvester, conservation of the biological resource base is economically irrational.

## 6. SOME EMPIRICAL EVIDENCE

Such outcomes can be cited from the U.S. experience with joint-venture (JV) fisheries in the North Pacific and Bering Sea, which began in 1978 and extended through 1990. In 1990, for example, the JV trawl fishery for flatfish in the Bering Sea was governed by a quota which specified the "allowable catch" of the target species (yellowfin sole and "other" flatfish). In addition, strict "bycatch" limits (or caps) were imposed on the JV operations for red king crab, Tanner crab, and Pacific halibut (collectively identified as "prohibited species catch" or PSC).

The halibut PSC cap was ultimately exceeded and the JV fishery was closed prior to completion of the harvest of the available flatfish quota. The interesting thing to note, with respect to the present discussion, is the daily rate of halibut bycatch that was recorded over the course of the JV flatfish season.

JV fisheries were monitored by on-board observers and catch data (both target and bycatch) were tracked, for in-season management purposes, on a fleet-wide basis. As the PSC quota for halibut was consumed, information concerning the remaining balance was made available to the fleet. As the PSC quota neared exhaustion, a management decision was made by the Alaska Region of NMFS concerning the closure of the fishery, and a projected closing date was announced to the fleet. As the data indicate, (see figure) the bycatch performance of the monitored fleet was relatively stable through the first weeks of the season, (with perhaps a slight upward trend owing, in part, to increasing competitive effort on the grounds and, perhaps, greater numbers of halibut moving into shallower waters as the season progressed). However, once exhaustion of the PSC cap was inevitable (and thus loss of access was imminent), concerns about "conservation" of the halibut resource were discounted in fishing decisions of the JV operators, as members of the fleet "raced" to maximize their individual catches of the target flatfish species. The result was an explosive rise in the halibut bycatch rate immediately preceding the announced closure date.

This pattern of behavior is evident throughout the data on U.S. JV fisheries. Often, the rapid acceleration of bycatch, in the face of an announced closure, resulted in the quota or cap being exceeded. On occasion, the overage proved to be quite substantial.

## 7. DIFFERING VIEWS OF THE FUTURE

While the contractual arrangements associated with U.S. JVs were certainly a far cry from the idealized cooperative arrangement described in the hypothetical example presented earlier, these empirical results suggest that the absence of "property interest" in the resource may effectively subvert a coastal nation's efforts to optimize (rationalize) the exploitation of its fish resources. That is, to the extent that conveyance of property interests is incomplete, due, for example, to insufficient duration of the access guarantee, imposition of EFJ regimes will not resolve the tendency to move to the open access solution. When the cooperating parties jointly share property interest in the resource, a long run biological and economic equilibrium solution becomes possible.

## 8. EXTENSIONS AND CONCLUSIONS

As Clarke and Munro have shown, when coastal and distant water partners have different rates of time preference (discount rates) it will be difficult, if not impossible, to design a contractual arrangement that has no incentive gap. Consequently, the resource will be exploited at a level that is not optimal from the coastal country's perspective.

If there are many potential partners bidding for access rights, however, it is possible that partners with identical discount rates will pair up, at least "at the margin". Inframarginal rents and surpluses would be no different in nature from those in any competitive market involving traders with a variety of taste and cost structures. The asymmetric information problem would be solved through lump sum payments.

Suppose, however, that no such equilibrium exists because the discount rates for all distant water fleets exceed the discount rates for all coastal countries. In this case, while there would be a divergence between access buyers and sellers regarding resource management desires, competitive bargaining should lead to trades that eliminate all Pareto-relevant externalities. Any tax/subsidy scheme imposed on the solution would lead to one party gaining at the expense of the other. Thus, even if the coastal country "hired" the services of distant water partners, if this were done on a competitive basis (competition among buyers and among sellers) the result would be the same.

It has been argued in this paper that a distant water fleet will harvest the resources of a coastal nation at the same rate whether it is hired by that nation or, instead, is a partner in a cooperative fishing arrangement (cfa). As discussed above, the validity of this argument depends upon two fundamental assumptions.

First, that the cfa involves the effective conveyance of "quasi-property interest" in the resource to the distant water operator. Through a contractual arrangement of sufficient duration the coastal country and the distant water fleet may be induced to jointly conserve and steward the resource base.

Second, it relies upon the presence of competitive market structures. That is, it depends on the condition that, if the distant water fleet did not offer an arrangement that was attractive to the coastal country, the latter could turn to competing fleets to obtain more attractive offers. Similarly, the fleets themselves are assumed to have numerous coastal water nations among which to negotiate a cfa partnership.

With respect to the second, is there in fact such a market ? Evidence suggests that one is emerging. As a consequence of EFJ, excess harvesting and processing capacity has led countries such as Norway, the USSR, and most recently the United States to seek partners in distant waters. Even fleets within countries are competing among themselves for access. Sullivan reports that fleets from the former Soviet Union vie with each other for Canadian partnerships in Atlantic Canada. With the ascendancy of the new republics, this competition may become even more intense. Countries are now advertising in international trade and fishing magazines for partners in joint-ventures. While data are scarce, a competitive market for access appears to be emerging [7].

In effect, as we see it, the three key elements which underlay the foregoing discussion include :

(i) the duration of access [which conveys an effective property interest in the resource to the distant water partner]
(ii) consideration of the respective rates of social time preference among the cfa partners ; and
(iii) the influence of asymmetric information on cfa arrangements. We contend that all three are inextricably linked. Specifically, contract duration and rate of social time preference are inversely related to one another.

In one sense, with respect to distant water operators, the higher the rate of social time preference the less important will be the duration of assured access under the terms of the cfa. For the coastal nation, the higher the rate, the less concerned they will be about granting long term access. In the limit, cfa partners with sufficiently high rates of discount may cooperatively engage in pulse fishing, extracting the maximum harvest in the shortest amount of time, without regard for future harvests. This result is contrary to the joint-venture outcome suggested by Kaczynski.

Furthermore, it is through a reasonably competitive market for access that (at least at the margin) partners with compatible expectations about contract duration, and thus similar rates of time preference, may be brought together.

The asymmetric information problem, cited above, is overcome in the presence of competitive conditions. That is, in the presence of many potential "buyers" and "suppliers" of access, unfair practices by one cfa partner, based on asymmetrically held information, need not be tolerated (endured) by the other partner. Furthermore, as suggested, once the distant water fleet has fishing rights of indefinite tenure, the coastal nation no longer has a monitoring problem and the asymmetric information feature disappears.

7. This development has been recognized in other quarters. The OECD has very recently acknowledged an emerging world market for access to fisheries resources and harvesting expertise. It has just undertaken an empirical study of the "joint-venture" market phenomenon, with the U.S. National Marine Fisheries Service as one of the principal participants.

Since the access market will tend to bring together suppliers and demanders who share expectations concerning contract duration (and, implicitly, rates of social time preference), relatively stable, mutually beneficial relationships will emerge through cfas, reflecting the "optimal" rate of resource use of the coastal (and coincidently of the distant water) nation.

This paper is in no way intended as a critique of the Clarke-Munro analysis. Rather, it should be regarded as an extension of that work, integrating their insights with those of our 1988 paper.

The reader is reminded that the arguments presented in this paper are in a preliminary state. While world events seem to suggest we are on the right track, the authors would welcome comments.

RÉSUMÉ

*La présence d'un certain consensus social sur l'importance de l'interaction environnement-économie relance à nouveau la question de l'intégration de l'environnement au système de comptabilité nationale. Plusieurs organismes multilatéraux et différents pays ont donc entrepris des travaux visant à réaliser une nouvelle comptabilité environnementale.*

*Peu de travaux ont cependant été réalisés pour les ressources halieutiques. Pourtant, l'intérêt d'une telle comptabilité de l'environnement ne se limite pas à la "correction" des comptes nationaux. Il s'agit aussi d'un système d'information pouvant constituer un outil de gestion important au niveau sectoriel. Cette intégration des informations économiques et biologiques devrait faciliter la gestion pluridisciplinaire, permettre de décrire le rôle des différents agents (qui paie et qui bénéfice) et constituer un outil de gestion rationnel pour la prise de décision.*

*La présentation communication vise à présenter cette problématique en s'intéressant en particulier au cas des ressources non-marchandes comme le saumon de l'atlantique.*

ABSTRACT

*The necessity to integrate the state of the environment in the indicator of economic development, is now recognized. Much research is being done on this topic by multilateral organisations and some countries. The methodology used and the framework developed differ with the different experiments but the objective is the same: to describe the variation of stock and flux of natural resources, and to present the interaction between this resource and the economic system.*

*The usefulness of this natural resource account is not only to "correct" the national account system, it is also an important tool for the management of this resource. The integration of economic and biological informations can facilitate the multidisciplinary management, gives better information about the role of different economic agents (who pays and who benefits) and provides a rational economic tool to help make a decision between the preservation of the environment and the development of economic activities.*

*The present paper wants to contribute to the development of this research for fisheries resource, especially for the resource with no price market. We present two of the most important research done on natural resource account, the few experiements done on the commercial fisheries and some aspects of the application of this approach for sport fishing, especially salmon fisheries.*

## 1. INTRODUCTION

La problématique de la prise en compte de l'environnement et des ressources naturelles dans la comptabilité nationale n'est pas nouvelle. On reconnaît depuis longtemps que cette comptabilité, basée essentiellement sur les flux financiers, ne tient pas compte de la dégradation de l'environnement et de l'épuisement des ressources naturelles. Parce qu'elle ignore certaines "fonctions" du milieu naturel, permettant notamment de fournir des ressources naturelles essentielles au système de production et d'assimiler une partie des résidus de ce système, la comptabilité nationale ne permet pas de porter un jugement sur le caractère soutenable des activités économiques.

Si cette problématique n'est pas récente, elle suscite aujourd'hui un nouvel intérêt pouvant s'expliquer entre autres par l'émergence d'un consensus social sur le rôle essentiel de l'interaction environnement-économie. En effet, si l'on considère que la dégradation de cet environnement peut avoir un effet sur la richesse des sociétés, on doit alors chercher à prendre en compte l'état de l'environnement dans la comptabilité nationale puisque ce système d'information doit décrire l'évolution de la richesse et permettre de répondre aux questions de la collectivité relative à cette richesse. De plus, la présente révision de l'ensemble du système de comptabilité nationale par le Bureau des statistiques des Nations-Unies a contribué également à relancer au niveau international la discussion sur cette perspective d'intégration environnement-économie.

Dans ce contexte, on peut maintenant affirmer qu'il "est assez bien établi que la comptabilité nationale devrait refléter cette dégradation environnementale. Mais il reste plusieurs controverses sur comment faire ces ajustements" (El Serafy, 1991).

La présente communication vise à présenter cette problématique et à explorer la pertinence d'une telle comptabilité pour les ressources halieutiques en général et de façon plus spécifique pour les ressources non-marchandes telles que le saumon de l'Atlantique au Québec.

La première partie de notre exposé présentera donc la problématique générale de la comptabilité environnementale en décrivant deux cadres conceptuels visant à réaliser cette comptabilité: le premier étant le système français de "Comptabilité du patrimoine naturel", le second étant le "Système intégré de comptabilité économique et environnementale" développé par le Bureau des statistiques des Nations-Unies. Nous présenterons ensuite brièvement deux cas concrets d'application pour les ressources halieutiques, le premier développé en Norvège et le second au Costa-Rica. Nous aborderons finalement le cas spécifique des ressources non-marchandes. Notons toutefois que nos travaux visant à élaborer un compte pour le saumon de l'Atlantique ne sont pas encore complétés. La présente communication se limitera donc à présenter la problématique générale d'une telle comptabilité sans présenter de compte chiffré.

## 2. LA COMPTABILITE DU PATRIMOINE NATUREL

L'objectif de tous les travaux de comptabilité de l'environnement est de refléter les interactions environnement-économie pour permettre d'orienter les décisions politico-économiques dans une perspective de développement soutenable. Si l'objectif est le même, la démarche employée varie beaucoup d'une expérience à l'autre.

Une des principales différences entre les approches proposées est l'importance accordée à l'évaluation monétaire de l'environnement et, par le fait même, à la possibilité d'élaborer des agrégats globaux. Pour certains, l'évaluation monétaire est l'élément central de cette comptabilité, permettant d'élaborer des agrégats économiques qui tiennent compte de la dégradation de l'environnement. Pour d'autres, l'évaluation monétaire n'occupe pas une place privilégiée dans le système, elle ne permet que de déterminer à quel point on s'est éloigné d'une situation jugée soutenable.

Le système de "comptabilité du patrimoine naturel", développé en France par la "Commission interministérielle des comptes du patrimoine naturel", représente un exemple de cette dernière tendance. Ce système de comptabilité environnementale, développé en parallèle à la comptabilité nationale, permet de colliger et de mettre en cohérence les diverses informations relatives aux éléments de ce patrimoine naturel tout en permettant d'établir un lien entre ces informations et celles de la comptabilité nationale traditionnelle. Ce système est considéré comme l'un des plus complet et des plus ambitieux dans ce domaine puisqu'il vise à décrire les dimensions écologique, économique et socio-culturelle de l'ensemble du patrimoine naturel pouvant être affecté par l'activité humaine.

Pour permettre une telle représentation des éléments du patrimoine naturel, le SCPN fut développé selon une approche modulaire comprenant trois pôles (figure 1). Le compte d'élément, élaboré pour un élément donné du patrimoine naturel, permet de décrire le passage entre le stock initial et le stock final à l'aide d'une description des différents flux physiques d'origine naturelle ou humaine (croissance et mortalité naturelle, prélèvement humain, ensemencement, etc). Le compte d'écozone décrit l'état de santé des écosystèmes où évolue cet élément ainsi que l'évolution de la répartition spatiale de cet élément. Finalement le compte d'agents devrait décrire l'interaction entre les êtres humains (et leurs institutions) et cette ressource. Les informations présentées dans ce compte sont de nature économique et physique et décrivent les dépenses de gestion et d'exploitation, l'évaluation de la valeur monétaire de cette ressource et des informations de nature socio-culturelle. La première étape dans l'élaboration de ce compte d'agents étant l'identification et le rôle de l'ensemble des intervenants permettant d'identifier les flux de l'ensemble de cette filière et de déterminer combien on dépense, qui finance, qui en bénéficie (INSEE, 1986).

Bien que cela ne soit pas considéré comme prioritaire dans le cadre des travaux français, on peut chercher à attribuer une valeur économique à cette ressource naturelle, ou plutôt une valeur à la variation de cette ressource. Se pose alors tout le problème de l'évaluation monétaire d'un bien environnemental, problématique bien différente s'il s'agit d'un bien marchand ou d'un bien non-marchand. Dans le premier cas on dispose, bien qu'il soit imparfait, du mécanisme des prix pour refléter la valeur de cette ressource. Dans le second cas, et c'est celui du saumon de l'Atlantique au Québec, ont doit "révéler des prix non-payés" (Pillet, 1992), ce qui pose des problèmes méthodologiques relativement complexes.

On peut pousser le raisonnement un peu plus loin et dire que ces informations économiques doivent non seulement être mises en relation avec les indicateurs économiques mais également servir à les corriger.

Un exemple de cette démarche est celle développée au niveau du Bureau des Statistiques des Nations-Unies en collaboration avec la Banque Mondiale et visant à élaborer un "Système intégré de comptabilité économique et environnementale" (SCEE) (Bartelmus et al., 1991). Dans la mesure où il n'existe pas de consensus international sur la façon d'évaluer et d'incorporer les coûts environnementaux, on ne propose pas modifier le cadre actuel de la comptabilité nationale mais plutôt de développer en parallèle à ce système un "compte satellite de l'environnement" pour intégrer cette nouvelle comptabilité économique et environnementale.

Ce Système intégré de comptabilité économique et environnementale propose d'étendre le concept de capital pour couvrir non seulement le capital d'origine humaine mais également le "capital naturel" (Bartelmus, 1992). On y définit également le revenu comme étant "le maximum qu'on peut consommer dans une période donnée tout en maintenant le capital initial..." (Potvin, 1991). Partant de ces deux principes, on peut considérer l'évaluation économique des dommages environnementaux comme une diminution de la valeur du capital naturel, comparable à la dépréciation du capital d'origine humaine. On peut ensuite corriger les agrégats macro-économiques, tel le Produit intérieur brut, pour tenir compte de la dépréciation du capital d'origine humaine ainsi que du capital naturel. On obtient ainsi de nouveaux indicateurs économiques tenant compte des coûts environnementaux engendrés par l'ensemble du système de production et de consommation. Ce nouvel indicateur, le "produit intérieur net ajusté de l'environnement", correspond donc au Produit intérieur net moins la valeur de l'épuisement des ressources naturelles et les coûts de la dégradation de l'environnement (Lutz et Munasinghe, 1991).

L'ensemble du système intégré de comptabilité économique et environnementale ne se limite pas à cette correction des agrégats. Il devrait permettre également:

- d'identifier et de séparer les activités de protection et de restauration de l'environnement permettant ainsi d'identifier la part du PIB nécessaire pour compenser les impacts négatifs de la croissance économique;

- et de décrire les liens entre la comptabilité physique des ressources naturelles et les évaluations économiques de la comptabilité nationale (Bartelmus, 1992).

Tout comme dans le cas du système français, la comptabilité physique constitue donc un élément de base de ce système. Toutefois, l'approche développée par le BSNU privilégie l'élaboration d'agrégats globaux permettant de refléter, en terme monétaire, la prise en compte de l'environnement dans la comptabilité nationale.

## 3. LA COMPTABILITE DES RESSOURCES HALIEUTIQUES

La plupart des informations biologiques ou économiques composant ces comptes sont familiers aux gestionnaires des pêches. Ainsi, les informations biologiques présentées dans le compte d'élément constituent des éléments traditionnels de la gestion des pêches permettant de décrire l'état du stock et ses principales sources de variation. Au niveau économique, on retrouve pour plusieurs pêcheries une évaluation des coûts et revenus associés à cette activité alors que l'évaluation de cette richesse peut être associée à la notion de rente ou surplus économique. Si certaines données sont courantes, on ne dispose pas cependant de cadre permettant de synthétiser l'ensemble de ces informations. La comptabilité de l'environnement fournie un tel cadre.

Peu de travaux de comptabilité ont donc été réalisés pour les ressources halieutiques. Parmi les rares travaux traitant de ces ressources, notons ceux réalisés en Norvège et au Costa Rica. L'approche retenue dans le premier cas est essentiellement biologique alors que dans le second elle est essentiellement monétaire. Elle permettent toutes deux de bien situer cette problématique pour les ressources marchandes.

L'expérience norvégienne constitue en fait l'expérience la plus ancienne de comptabilité des ressources naturelles (les premiers comptes ont été présentés en 1974) et la seule qui soit actuellement opérationnelle.

La structure théorique des comptes comprend trois éléments soit les comptes de stock, de commerce et d'utilisation. Le premier décrit l'évolution de la ressource entre la période T0 et T1, le second décrit les échanges commerciaux reliés à cette ressource et le troisième constitue un bilan matière pour les différents secteurs de l'économie norvégienne. En pratique toutefois, "une ressource biologique comme le poisson requiert un compte de stock relativement bien détaillé avec des spécifications sur la structure de l'âge et la localisation des différentes classes et types de poissons. La partie III du compte - le compte d'utilisation- est toutefois relativement simple puisque quelques secteurs utilisent le poisson comme intrant dans leur production... De façon similaire, l'importance du commerce extérieur des ressources détermine l'accent mis sur la partie commerce du compte" (Alfsen et al., 1986).

Les informations que l'on retrouve dans cette comptabilité des ressources halieutiques constituent donc essentiellement des informations de nature biologique: biomasse, nombre de géniteurs, indice de recrutement, quotas et prises. On y retrouve également des informations illustrant le partage des stocks entre la Norvège et ses principaux partenaires ainsi que des informations économiques sur l'importance de ce secteur dans le commerce extérieur norvégien (CBS, 1989 et 1992).

Cette approche essentiellement biologique, peu intégrée aux informations économiques, n'apporte pas d'informations supplémentaires par rapport à la gestion traditionnelles de cette ressource. Il n'est donc pas surprenant de constater que ces données soient peu utilisées et que leur mise à jour ne soit pas régulière (Asbjorn. et al., 1991). Une comptabilité environnementale essentiellement physique n'apporte donc aucun élément nouveau pour ces ressources qui sont déjà gérées sur la base d'un rendement soutenu.

L'approche adoptée au Costa Rica est différente puisqu'il s'agit d'une approche essentiellement monétaire; différence toutefois plus faible qu'il n'y parait à première vue puisque l'évaluation physique est un prérequis à l'évaluation monétaire et cette dernière n'est que la multiplication d'une quantité physique par un prix ou un pseudo-prix (Weber, 1991). Cette étude s'inscrit dans le cadre des travaux de World Resources Institute de Washington visant à évaluer la dépréciation du capital naturel, au même titre que l'on évalue la dépréciation du capital d'origine humaine. Une telle évaluation permettant de corriger directement les agrégats nationaux, tel le PNB, pour mieux refléter l'aspect soutenable

de la croissance économique (Repetto, 1989). Moins ambitieuse que les cadres théoriques présentés précédemment, cette comptabilité ne vise qu'à prendre en compte la dépréciation de certaines ressources naturelles exploitées commercialement.

L'approche retenue pour l'évaluation de la dépréciation des ressources halieutiques au Costa-Rica est classique (Repetto, 1991). L'évaluation de l'effort de pêche et de la biomasse permet de déterminer le rendement soutenu de la pêcherie pour ce niveau donné d'effort de pêche. On est alors à même de déterminer la rente annuelle que peut générer cette pêcherie; rente définit comme les revenus annuels provenant de ce rendement soutenu moins les coûts totaux, incluant le retour sur le capital et le coût d'opportunité du travail. Cette rente annuelle est ensuite actualisée pour obtenir la valeur économique de la pêcherie. La figure 2 illustre le déclin de la valeur de ce capital suite à l'augmentation de l'effort de pêche et la diminution du rendement soutenu. Notons toutefois que ces évaluations ne sont obtenues qu'au prix de nombreuses estimations pour pallier aux lacunes du suivi statistique.

La mesure de la dépréciation, ou de la perte en capital provenant de la surexploitation de la ressource, est obtenue en ne considérant que la variation annuelle de la valeur de la pêcherie résultant de la diminution du rendement soutenu; les variations résultant d'un changement de prix ou de coûts de production n'étant pas considérées comme une dépréciation. L'effet de cette dépréciation peut être illustrée en comparant l'évolution de la valeur brute et de la valeur "nette" de cette production (figure 3).

Précisons toutefois qu'il ne s'agit pas de déterminer un sentier optimal d'exploitation mais bien de déterminer l'effet d'une modification du niveau d'exploitation sur la richesse que peut générer à long terme cette ressource. Une telle comptabilité ne permet donc de juger que du caractère soutenable du revenu engendré par cette activité.

## 4. LA COMPTABILITE D'UNE RESSOURCE NON-MARCHANDE

Les deux exemples que l'on vient de présenter ne décrivent chacun qu'un aspect de la gestion de ces ressources exploitées sur une base commerciale; dans le premier cas on décrit le bilan physique et dans le second on évalue le revenu soutenable. La comptabilité que nous cherchons à réaliser pour les ressources non-marchandes ne cherche pas uniquement à décrire un indicateur agrégé, physique ou monétaire, mais vise à élaborer un système d'information plus complet permettant une meilleure gestion de la ressource. Dans ce contexte, les travaux français de comptabilité du patrimoine naturel nous semble pertinent puisque cette approche permet de décrire l'ensemble des caractéristiques de cette ressource tant d'un point de vue écologique qu'économique.

Le bilan physique constitue l'élément de base d'une telle comptabilité et devrait permettre de décrire les changements dans l'état de la ressource survenus durant la période d'étude.

Toutefois, une telle approche ne permet pas de décrire toute la problématique et doit être complétée par un ensemble d'évaluation économique.

La première démarche au niveau de cette évaluation monétaire vise à décrire l'ensemble des flux financiers et des sources de financement reliés à cette ressource. Dans le cas spécifique qui nous intéresse, on pourra élaborer une "dépense saumon totale" comprenant les dépenses des pêcheurs ainsi que les dépenses de gestion, de restauration du milieu naturel et d'exploitation permettant d'offrir des services de pêches récréatives. On pourra ensuite identifier les différentes sources de revenus associées à ces dépenses. Mis à part la difficulté d'identifier ces flux pour une espèce spécifique, telle le saumon, une telle évaluation ne pose pas de problème méthodologique particulier.

L'évaluation monétaire du capital naturel est plus délicate. En l'absence de prix de marché (on peut considérer que c'est le cas pour le saumon de l'Atlantique au Québec puisque moins de 50 % des prises sont effectuées par des pêcheurs commerciaux (Caron et Shields, 1991), on doit estimer le bénéfice associé à cette espèce à l'aide de l'évaluation du consentement à payer. Idéalement, on devrait évaluer non seulement la valeur d'usage mais également la valeur d'existence reliée à cette ressource, soit la "valeur économique que les individus accordent au fait qu'ils savent que la ressource existe dans la nature" (Bergstrom et al. 1990). On obtient ainsi ce que David Pearce qualifie de "Valeur économique totale" (1990), ou le bénéfice total associé à cette ressource pour l'ensemble de la société. Cette valeur économique totale correspond donc aux dépenses effectivement réalisées plus le consentement à payer une somme excédentaire pour l'usage ou la préservation de cette ressource.

Différentes techniques d'évaluation sont disponibles pour évaluer cette valeur. La méthode d'évaluation contingente est généralement la méthode recommandée pour évaluer ce consentement à payer puisqu'elle est la seule qui permette d'évaluer la valeur d'existence (Mitchell et Carson, 1989). On retrouve d'ailleurs dans la littérature plusieurs exemples d'évaluation contingente pour évaluer le bénéfice associé à cette espèce (Hager et al;, 1989; Bonnieux et al., 1992). Cette évaluation contingente peut toutefois être difficile à appliquer dans le cas du saumon au Québec puisqu'on y retrouve plusieurs modes d'exploitation: pêche sportive, pêche de subsistance pratiquée par les amérindiens, pêche commerciale et, en plus, une pêche d'interception en mer le long des côtes du Groenland.

Une autre alternative serait d'évaluer les coûts associés à la restauration, ou au rétablissement de la capacité écologique du milieu, principe retenu par le BSNU dans le cadre du système intégré de comptabilité. Pour obtenir une telle évaluation, il faut estimer les coûts éventuels de restauration nécessaires, soit pour rétablir la qualité de l'environnement à son niveau initial au début de la période comptable, soit pour ramener à un niveau établi selon les normes environnementales officielles (Potvin, 1991). Reste toutefois à déterminer ce qu'est le niveau initial et à distinguer parmi les causes de cette variation celles qui sont d'origine naturelle.

Notons toutefois que les résultats que l'on pourrait obtenir par ces deux techniques sont forcément différents. La méthode contingente évalue le coût de maintenir constant le bénéfice associé à cette ressource. La méthode des coûts de restauration évalue le coût de maintenir constant le stock physique de cette ressource. Le choix de la méthode d'évaluation n'est donc pas neutre et peut être considéré comme une certaine vision du concept de développement durable.

Finalement pour que le portrait de l'ensemble de la filière soit complet il faudrait y inclure, dans l'optique de la comptabilité du patrimoine naturel, des informations de nature écologiques et culturelles. Dans le premier cas, il n'est pas nécessaire de chercher à décrire l'ensemble du fonctionnement de cet écosystème. On peut se limiter à utiliser des indicateurs de qualité du milieu ainsi que des informations décrivant la superficie du territoire accessible. Une telle évaluation permettant de situer cette espèce dans un contexte plus large, le poisson n'étant que le produit d'une ressource plus globale qu'est l'écosystème marin (Reveret, 1991). Cette approche plus systémique soulève cependant une question délicate, soit la différence que l'on fait entre la gestion de la ressource et la gestion du milieu où évolue cette ressource. En ce qui concerne le volet socio-culturel, on pourrait présenter un ensemble d'informations permettant de décrire des composantes culturelles qui ne sont pas pris en compte par l'évaluation des coûts. Ce dernier volet fait toutefois l'objet de très peu de travaux pratiques.

## 5. CONCLUSION

L'intérêt de cette comptabilité environnementale se situe au moins à deux niveaux. Au niveau national, elle permet de mieux suivre l'évolution du capital naturel et de mieux intégrer l'environnement dans les décisions politico-économiques. Mais il nous semble que c'est surtout au niveau sectoriel qu'une telle démarche est la plus utile. En regroupant dans un même cadre d'analyse toutes les informations physiques et monétaires relatives à une espèce ainsi que les informations décrivant l'état de l'écosystème où évolue cette espèce, on se dote d'un outil de gestion facilitant l'intégration des considérations économiques et écologiques dans une perspective de gestion pluridisciplinaire des ressources naturelles.

Dans cette optique, les données physiques sont nécessaires pour décrire l'interaction environnement économie mais elles ne sont pas suffisantes. L'identification des flux monétaires, soit l'ensemble des dépenses et de leurs sources de financement, constitue un élément de gestion important permettant d'identifier le rôle de l'ensemble des intervenants. Quant àl'évaluation monétaire, elle permet de déterminer les coûts nécessaires pour retrouver une situation considérée comme soutenable. Il ne faut pas cependant pas perdre de vue que cette démarche reste encore dans une phase exploratoire, en particulier pour l'ensemble des ressources environnementales ne possédant pas de prix de marché. L'évaluation monétaire constitue donc un aspect très controversé dans la comptabilité environnementale "requérant des travaux exploratoires pour arriver à une méthodologie standardisée acceptable" (BSNU, 1991). La ressource halieutique constitue selon nous un objet d'étude pertinent pour faire avancer cette problématique.

# Fishing and Development
# by
# J. Catanzano

Traitée dans cette session selon différentes acceptions et différents points de vue, la question du développement reste à l'heure actuelle, tant sur le plan des économies nationales des pays côtiers les plus défavorisés que sur le plan des secteurs de production halieutique, l'une des questions fondamentales adressée à l'ensemble des sciences sociales intéressées aux ressources, espaces et sociétés littoraux. En effet, force est de constater que dans le monde actuel, les ressources halieutiques tendent à devenir pour quelques-uns des pays en développement les principales richesses porteuses des plus grandes potentialités sociales et économiques. Trois éléments suffisent à illustrer ce constat. Tout d'abord le poids qu'elles représentent dans les échanges internationaux, devenant souvent les premières sources de devises pour les pays en voie de développement au détriment d'autres secteurs de production agricole ou minier bien souvent en repli (cas de la Mauritanie, de Madagascar, du Sénégal...). Ensuite le rôle que joue dans les pays côtiers les activités économiques de production, de transformation ou de commercialisation des produits de la mer, tant du point de vue des richesses créées que de celui des emplois. Les économies littorales s'en trouvent ainsi revitalisées. Les activités de pêche permettent la fixation des hommes sur la bande côtière dans des pays souvent enclins par le passé à de fortes migrations humaines vers des zones économiquement viables (sites urbains ou industriels) de pays voisins ou pays développés. Enfin de part la nature même des produits halieutiques, la pêche joue un rôle croissant dans la satisfaction des besoins alimentaires des populations locales devenant en bien des cas la source essentielle de protéines animales.

La nouvelle répartition des richesses halieutiques née du nouveau droit de la mer confère aux pays en développement de nouvelles responsabilités d'exploitation et de gestion de leurs ressources dans un monde où les systèmes de production se sont internationalisés, où se sont transformées tout récemment encore les capacités

In this session the problem of development is dealt with in all its meanings and from various points of view. It remains one of the most fundamental questions for all the social sciences interested in coastal resources, spaces and communities, whether one is looking at the poorest coastal countries national economy or the fisheries production sector. Indeed, we cannot but notice that in today's world, fisheries resources have tended to become the main source of wealth for some developing countries, bringing with them great economic and social possibilities. Three points suffice to illustrate this statement. First, the importance that they have in international exchange, often becoming the major source of hard currency for developing countries and this at the expense of other sectors of production such as agriculture and mining which are often in decline (as the case in Mauritania, Madagascar, Senegal...). Second is the role that the whole range of economic activities, involving, production, processing and marketing of sea products, play in the creation of wealth and jobs in coastal countries. In this way coastal economies have been revitalised. Fishing has helped to fix populations in the coastal zones in countries which, in the past, have often witnessed large scale human migration towards economically viable areas (such as urban or industrial sites) in neighbouring or developed countries. And finally, the very nature of fisheries products gives fishing and increasing role in achieving food security for local populations, becoming in many cases the main source of animal protein.

The distribution of fisheries resources, resulting from the new Law of the Sea gives developing countries new responsibilities for the development and management of resources in a world with new international production systems, which has very recently seen the transformation of potential productive capacities of big industrial blocks (such as Eastern Europe, Asia, European Union), and where the trend is increasingly towards the globalisation of markets. All this contributes to the growing instability

productives mobilisables par les grands blocs industriels (pays de l'Est, Asie, Union européenne...), où se sont accélérées aussi les tendances à l'internationalisation des marchés. Tout cela exacerbe à la fois l'instabilité et l'incertitude des facteurs à prendre en compte dans les stratégies nationales. De fait, ce sont autant de difficultés supplémentaires qui en découlent face à des pays encore dépendants en grande partie des capacités productives extérieures. La question du développement abordée selon les différentes facettes précédemment évoquées renvoie l'observateur ou scientifique devant l'obligation de prendre en compte différentes échelles socio-politico-économiques depuis les économies et stratégies internationales jusqu'aux économies locales.

A côté de cela, la question du développement tend à contenir l'une des interrogations majeures du monde actuel, non spécifique à la pêche, même si celle-ci en fournit une illustration intéressante, consistant à chercher les bases d'un nouveau paradigme pour l'exploitation des ressources naturelles renouvelables selon le concept d'un développement durable. On verra que certaines propositions sont discutées dans cette session qui ouvrent sur une révision des paradigmes anciens attachés aux dynamiques de l'exploitation des ressources halieutiques.

Mais l'accession au développement, tant sectoriel que global pour des économies nationales, ne va pas sans poser elle aussi un certain nombre de questions. Ainsi on peut se demander quelles sont les modalités les plus efficientes d'appui au développement ? Quelles sont les politiques globales et initiatives locales les plus appropriées ? Que peut-on tirer des leçons des tentatives passées plaquées sur l'ensemble des secteurs de production primaire avec des schémas de spécialisation productive et commerciale souvent fondés selon des modes de production très artificialisés (cultures d'exportation à côté des cultures vivrières par exemple) ? Que dire des projets de développement ?

N. Sinkam et J. Weber, dans leur communication respective, abordent ces différentes questions adressant au passage quelques critiques aux schémas artificiels plaqués trop souvent sur les sociétés traditionnelles en guise d'accession au développement. Fondés essentiellement sur l'Afrique, leurs propos gardent du point de vue des questionnements et souvent même des constats, une applicabilité quasi universelle tant sont communs souvent les modèles promus par des acteurs extérieurs au PED.

Les autres auteurs qui s'expriment dans cette session illustrent assez largement aussi quelques-unes de ces questions utilisant pour cela des références *a priori* différentes dans leur contexte géographique, social, his-

and uncertainty concerning the factors which have to be taken into account in national strategies. In fact, these are just so many more difficulties for countries which, for the most part, still depend on external productive capacity. Such a multifaceted approach to the problem of development requires the observer or the scientist to take account of various socio-politico-economic scales ranging from international economies and strategies to local economies.

In addition, the problem of development tends to include one of the major questions facing today's world, not really specific to fishing even though fishing represents and interesting example, a question concerned with the search for the bases of a new paradigm involving the exploitation of renewable natural resources within the concept of a sustainable development. We will see that some proposals are discussed in this session as a first step towards revision of the old fisheries paradigm which is concerned with the dynamics of fisheries exploitation.

But the development process, whether from a sectoral or global point of view in the national economy, also raises a number of questions. For instance, what are the most efficient ways and means of supporting development ? What are the most appropriate global policies and local initiatives ? What lessons can be drawn from previous attempts grafted onto the whole of the primary production sector with plans for productive and commercial specialisation often founded on very articificial modes of production (export crops next to food crops for example) ? What can be said about development projects ?

In their respective papers, N. Sinkam and J. Weber deal with these different questions while expressing some criticisms of the artificial plans grafted onto traditional societies in the hope of achieving development. Although founded mainly on African experience, the questions that they ask and even their answers remain practically universally valid as the models promoted by those outside the LDCs are so similar.

Other authors in this session also discuss some of these questions using references which seem to be a priori different in their geographical, social and historical context but which, in many respects allow us to understand the duality of development, considering some fisheries in developed countries in some cases. It is in particular the case of the snow-crab fishery in the gulf of St Lawrence used by J.C. Brêthes to try to understand and explain the dynamics of this productive sector by deciphering the role of each economic and social agent placed in a social an economic frame within different systems. Beyond the example's own conclusions, it is a perfect illustration of the way that the question of development can be applied to countries considered already beyond that issue.

torique, mais qui à bien des égards nous donnent l'occasion de comprendre la dualité d'un développement, perçu en quelques cas à propos de pêcheries en pays développés. C'est le cas notamment de la pêcherie du Crabe des Neiges dans le Golfe du Saint-Laurent à laquelle fait référence J.C. Brêthes pour tenter de comprendre et expliciter la dynamique de ce secteur de production en décryptant le rôle de chacun des acteurs économiques et sociaux placé dans un cadre de représentation sociale et économique construite en différents systèmes. Au-delà des conclusions propres à l'exemple traité, il s'agit là d'une illustration parfaite de l'applicabilité de ce questionnement du développement à des pays pourtant considérés comme déjà dégagés de cette question.

M. Kebe s'intéresse quant à lui aux modalités et exigences qui s'imposent dans les relations entre partenaires du nord et du sud, dans le nouveau contexte mondial d'obligations nées du nouveau droit de la mer. On y retrouve mêlés les objectifs sociaux des uns et les objectifs économiques des autres. On prend conscience également sur la base d'un cas concret des difficultés encore fortes qui viennent freiner les substitutions voulues dans les systèmes productifs. Le développement doit ainsi se conduire encore en bien des cas en coopération au travers de conventions ou contrats d'exploitation particuliers. L'auteur s'appuie dans ces propos sur les relations qu'entretiennent les Etats africains et l'Union Européenne, s'interrogeant notamment sur les avantages et risques de différentes solutions de partenariat.

Revenant à un niveau d'interrogation plus global, A.T. Charles et A. Herrera développent leur analyse des formes sociales coopératives de pêcheries du Costa Rica en se référant à quelques aspects fondamentaux de l'idée de développement que l'on retrouve aujourd'hui exprimés de plus en plus dans le concept de développement durable. Les auteurs mettent en avant une sorte de triptyque ou triangle susceptible de rassembler les conditions de durabilité que l'on doit rechercher dans les pêcheries. Au travers de cette vision se regroupent plusieurs conditions nécessaires. Ce sont différents domaines qui participent du système pêche et donc différents points de vue qui se retrouvent sur chacun des sommets. Assurer la durabilité du système et de son développement nécessite alors, selon les auteurs, une durabilité combinée des éléments écologiques, des éléments sociaux et économiques ainsi que des éléments institutionnels. Fédératrice, cette vision schématique permet également d'insister sur la pleine participation au système pêche d'éléments a priori plus extérieurs qui tendent à jouer un rôle essentiel dans la dynamique des pêcheries. Le développement durable, défini ainsi et appliqué à ce secteur, correspond à un développement

M. Kebe is interested in modalities and requirements essential to the relationships between North and South partners, in the new world background of duties resulting from the New Law of the Sea. The social objectives of some tend to be mixed with economic objectives of others. And a case study shows that very real difficulties emerge which act as a check upon the desired substitutions in the production systems. In many cases development must then still be organised on a cooperation basis through conventions of particular exploitation contracts. The author's remarks are based on relationships between African countries and the European Union and query in particular the advantages and risks linked to different parternship solutions.

Returning to a more general level of enquiry, A.T. Charles and A. Herrera develop an analysis of cooperative social forms of fisheries in Costa Rica by referring to some fundamental aspects of the idea of development that we find increasingly expressed today in the concept of sustainable development. The authors put forward a kind of three-phase plan or triangle supposed to bring together the conditions for sustainability that we must look for in fisheries. This way of looking at things clarifies the necessary conditions. These are different areas involved in the fishery system and hence different points of view are found at each apex. According to the authors, ensuring a sustainable system and its development depends on a combination of ecological, social and economic as well as institutional factors. Favouring a collective approach, this schematic vision insists that all elements participate fully in the fishing system, even those which are a priori more external but tend to play an essential part in the dynamic of the fishery. Sustainable development, as defined and applied to this sector, is a development which tends not to compromise the renewal of resources, social cohesion and the means of social regulation and also to keep institutions on their appropriate evolutionary path. Such a schematic representation as a "beneficial" triangle allows the identification of the conditions necessary to the success of development projects.

qui tend à ne pas compromettre le renouvellement des ressources, la cohésion sociale et modes de régulation sociaux, et garder aux institutions une trajectoire d'évolution qui leur est propre. La représentation schématique sous forme d'un triangle « bénéfique » permet de poser clairement certaines des conditions requises pour l'aboutissement de projets devant servir le développement.

# Quelle Place pour les Pêches Africaines dans le Cadre de la Nouvelle Donne Mondiale ?

**Samuel C. Nana Sinkam**

Commission des Nations Unies pour l'Afrique, Directeur de la Division Conjointe CEA/FAO de l'Agriculture (JEFAD), PO Box 3001 Addis Abeba, Ethiopie

ABSTRACT

*The objective of this document is to analyse and discuss on the development of the fisheries sector in Africa and on its role in the world exchanges of fishery products. In the framework of the new world deal of the 90's and facing the external constraints of the fisheries sector, many questions are raised. They concern both the future relations between Africa and its economic partners, and also the choices that Africa has to formulate to go ahead with the development of its fisheries.*

*Illustrated by precise and concrete examples, the following points are reviewed :*

- *Importance of the fisheries sector in Africa versus its disorganization.*
- *Specific problems of the fisheries sector and the african economy in general.*
- *New world context and the consequences for Africa.*
- *Main strategies for a sustainable development of fisheries activities in Africa.*

*Lastly, concrete recommendations are proposed, which should be implemented by african countries, and also accepted and assumed by their partners from the North within the framework of a genuine co-operation and real partnership.*

RÉSUMÉ

*L'objectif de cette intervention est de discuter du développement du secteur halieutique en Afrique et de sa place au sein des échanges halieutiques mondiaux. Dans le cadre de la nouvelle donne mondiale des années 90 et face aux externalités du secteur des pêches, des questions décisives se posent. Elles concernent aussi bien les relations à venir de l'Afrique avec ses partenaires économiques, que les choix qu'elle doit formuler pour poursuivre le développement du secteur.*

*Illustrés par des exemples précis et concrets, les points suivants sont abordés :*

- *L'importance du secteur des pêches en Afrique, malgré sa désorganisation ;*
- *Les problèmes spécifiques au secteur des pêches africain, et à l'économie africaine en général ;*
- *Le nouveau contexte mondial et ses conséquences pour l'Afrique ;*
- *Les stratégies possibles pour un développement soutenu des pêches en Afrique.*

*Enfin des recommandations concrètes sont proposées, qui devraient être mises en oeuvre par les pays africains, mais aussi acceptées et assumées par leurs partenaires du Nord, dans le cadre d'un partenariat véritable.*

## 1. INTRODUCTION

La production halieutique africaine, après avoir augmenté de 25 % de 1985 à 1988, connaît depuis une légère régression, due à la pleine exploitation des stocks. Parallèlement, près de la moitié des ressources marines sont encore exploitées par des flottes étrangères, sur un potentiel estimé à 9 millions de tonnes. De plus, la production africaine est relativement concentrée, 10 pays représentant 70 % de cette production. Pour le continent et pour ces pays en particulier, le secteur est vital, tant sur le plan de l'emploi (9 % des emplois agricoles) que sur celui de l'apport protéique (près de 50 % des apports de protéines animales).

De plus depuis vingt ans, on assiste à une chute des parts de marché de l'Afrique dans le commerce mondial. De 3,8 % en 1970, la valeur des échanges africains dans les échanges mondiaux est passée à 1 % en 1990. Ce ralentissement des échanges s'observe tant sur la valeur globale des produits exportés que sur celle des produits d'importation.

Or si, depuis dix ans, les valeurs en dollars constants de l'ensemble des exportations africaines, y compris celles du secteur agricole sont en baisse, la valeur en dollars constants des exportations de produits halieutiques africains n'a cessé d'augmenter et a été multipliée par trois sur la période 1980 à 1989 (cf. **encadré 1**).

Si l'on considère l'Afrique dans son ensemble, le secteur agricole est un importateur net en valeur en 1989 ; a contrario, le secteur des pêches dégage un excédent commercial et contribue à l'entrée de devises fortes dans les économies africaines (cf. **encadré 1**).

C'est dire combien les activités primaires halieutique et aquacole constituent pour certains pays africains des facteurs et des sources de croissance, dans un contexte de besoins nutritionnels importants :

- apport alimentaire,
- apports en devises fortes,
- investissement des plus values dégagées par la pêche dans les secteurs industriels,
- emploi...

Ce secteur important de l'économie africaine risque cependant d'être très touché dans les années à venir par les modifications de son environnement extérieur. La mondialisation actuelle des échanges, le développement des marchés des produits aquatiques dans les pays du Nord et les récents bouleversements politiques et économiques dans les pays de l'Est doivent et devront être pris en compte dans les nouvelles politiques et stratégies de développement, les anciennes orientations étant bien souvent obsolètes face à cette "nouvelle donne mondiale".

Le secteur des pêches devra s'adapter à ces nouveaux paramètres, en tenant compte des besoins importants (nutritionnels, devises) à satisfaire, des spécificités existantes (complémentarité ou compétition entre les pêcheries artisanales et industrielles) et des grandes tendances économiques, sociales et politiques africaines (croissance démographique, exode rural).

## 2. LE SECTEUR DES PECHES EN AFRIQUE, DESORGANISE MAIS D'UNE IMPORTANCE CAPITALE

Deux types d'exploitation fondamentalement différents coexistent à l'heure actuelle en Afrique : les pêches artisanales (barques, pirogues) et les pêches industrielles (flottes africaines - flottes étrangères). Tenant compte de ces différents types

d'exploitation, la production halieutique africaine en 90 se décompose comme suit : sur un total de 7,8 MioT, 1,3 MioT proviennent des eaux continentales, le reste, soit 6,5 MioT provenant des eaux marines. La production continentale est largement dominée par les pêches artisanales, les seules pêcheries industrielles ou semi-industrielles se trouvant dans les grands lacs du Rift. La production marine, quant à elle, comprend 3,3 MioT pêchées par les flottes industrielles étrangères et 3,2 MioT par les flottes africaines, desquelles environ la moitié sont produites par les pêcheries artisanales.

Au total, les pêches artisanales comptent pour environ les deux tiers de la production nationale africaine.

Du fait de la surexploitation de certaines ressources, on observe actuellement une concurrence accrue entre l'artisanal et l'industriel. A cette compétition pour l'espace et la ressource se surajoute une compétition pour les aides publiques et la commercialisation, où la pêche industrielle est généralement favorisée. A côté de ces problèmes intra-africains, se pose celui de l'exploitation des stocks hauturiers par les flottes étrangères : mauvaise négociation des accords de pêche, pêches illicites mais aussi vide laissé par le retrait des flottilles de l'Est.

Cette situation difficile est favorisée et compliquée par la faiblesse des structures administratives, des moyens humains et financiers disponibles pour organiser le secteur, au niveau national comme au niveau régional.

A ce titre, la création des ZEE par le nouveau Droit de la Mer en 1982, si elle est une chance pour l'Afrique, en lui octroyant la gestion de son espace maritime, représente également une difficulté de taille par l'augmentation des besoins organisationnels qui en découle, la tâche étant compliquée par une profonde méconnaissance du secteur (absence de statistiques fiables sur les ressources, l'exploitation, l'emploi, la rente économique,...). De fait, la plupart des pays africains ont encore d'importantes difficultés à gérer cette ressource qui leur a été confiée.

Quant au secteur aquacole, il compte environ pour 110 000 tonnes dont les deux tiers produits par un seul pays, l'Egypte. L'aquaculture "de subsistance" du tilapia, que l'on a cherché à développer en Afrique sub-saharienne depuis de nombreuses années, a toujours ou presque été un échec, dans lequel nombreux sont ceux qui continuent à persévérer. Il serai là aussi temps de regarder vers de nouvelles orientations (crocodiles, crevettes, acadjas,...) pour que l'Afrique participe enfin à l'expansion mondiale de l'aquaculture.

Malgré sa désorganisation, le secteur halieutique reste d'une importance cruciale en Afrique, tant sur le plan de l'emploi (2 millions de pêcheurs, 8 millions d'emplois induits) que sur celui des échanges (excédent commercial de 600 millions de $ en 89) et, enfin et surtout, sur le plan de l'apport protéique : malgré la relative faiblesse des approvisionnements (7,9 kg/hab/an contre un niveau mondial de 12,3 kg/hab/an), le poisson est une source majeure de protéines animales pour l'Africain, et une source qui vaut par la stabilité de ses apports (moins sensible que le bétail aux variations climatiques et à la compétition pour l'espace, dans un contexte de croissance démographique). Cependant, pour maintenir sa place dans l'avenir, compte tenu d'une croissance démographique de 3 % par an, l'approvisionnement en poisson de l'Afrique devra augmenter chaque année de 50 000 tonnes dans les années à venir.

Pour relever ces défis africains, il faudra prendre en compte les spécificités des ressources halieutiques africaines, leurs modes d'exploitation et le cadre socio-économico-politique africain, mais aussi l'évolution du contexte mondial dont l'impact sur l'Afrique ne fera qu'augmenter avec la mondialisation des échanges.

## 3. QUELS PARAMETRES ESSENTIELS POUR LE DEVELOPPEMENT DES PECHES AFRICAINES ?

### *3.1 Le contexte particulier des pêches africaines*

#### 3.1.1 Une demande en augmentation, une production à son maximum

Face à la croissance démographique, les besoins alimentaires africains ne cessent d'augmenter, et particulièrement les besoins en protéines, satisfaits pour une large partie par le poisson dans nombre de pays africains.

Les gros consommateurs africains (Nigéria, Zaïre, Côte d'Ivoire,...) doivent avoir recours aux importations pour satisfaire la demande de leurs populations. Or les importations intra-africaines sont largement entravées par les difficultés

d'acheminement des produits (manque d'infrastructures et de voies de communication), et les importations extérieures à l'Afrique sont quant à elles limitées par le manque de devises chronique de la plupart des pays africains. Ainsi, malgré une demande croissante, les importations ne peuvent augmenter.

Pour ce qui est des ressources halieutiques africaines, elles sont, comme partout dans le monde, pleinement exploitées, mise à part une fraction des ressources continentales. Une augmentation substantielle de la production ne pourra donc être obtenue sans un effondrement rapide des stocks, sauf à s'approprier l'exploitation de stocks exploités jusqu'à présent par des flottes étrangères.

#### 3.1.2 Un fait majeur : la prééminence politique des villes sur les campagnes, de l'industriel sur l'artisanal

La concurrence que nous avons mentionnée entre pêches artisanales et industrielles se rattache à un phénomène plus large de domination des villes sur les campagnes.

Cette domination est au départ politique, le pouvoir et les richesses étant concentrés dans les villes, la population urbaine étant la seule à représenter un danger potentiel pour les gouvernements. Cela se manifeste par des politiques d'alimentation faciles (importations, aide alimentaire) et une ponction sur le secteur rural, seul productif, des ressources nécessaires aux gouvernements et au maintien du niveau de vie dans les villes, par une politique de prix "artificiels".

En ce qui concerne les pêches, on observe de même des politiques favorisant la pêche industrielle, du fait d'un apport direct en devises (accords de pêche, licences négociés par l'Etat), mais aussi d'un contrôle plus facile des débarquements, centralisés dans les agglomérations portuaires, voire même simplement pour une raison de prestige. La pêche artisanale, au contraire, est disséminée le long des côtes et des fleuves, et les tentatives de des Etats pour la contrôler (coopératives, centres de commercialisation) ont toujours été des échecs. De plus, sur les mêmes ressources, elle est plus compétitive que la pêche industrielle et parvient parfois à l'évincer ( cas du lac Tanganyika dans sa partie burundaise, où les captures de pirogues ne cessent d'augmenter, les captures industrielles étant en diminution). Enfin la pêche artisanale est non seulement plus productive, plus génératrice d'emploi mais nécessite aussi un investissement en capital, et partant en devises, bien moindre. Par contre, l'accès aux stocks est dans son cas bien moins contrôlable que pour la pêche industrielle et, afin d'éviter la surexploitation, il sera nécessaire si l'on veut développer la pêche artisanale de mettre en place de nouveaux moyens de régulation de l'accès.

Alors que la tendance générale est à une croissance des villes aux dépens des campagnes, à une concentration croissante des activités, le secteur des pêches peut être l'un des premiers à renverser cette tendance ou du moins à la freiner, l'indépendance de l'activité artisanale par rapport à l'Etat étant relativement forte, et sa rentabilité étant élevée. Il peut donc jouer le rôle d'un exemple au sein du secteur agricole, et montrer qu'il est essentiel de promouvoir le secteur rural, seul générateur de richesses indispensables à l'investissement productif.

### *3.2 Des enjeux mondiaux et globaux, aux répercussions certaines*

#### 3.2.1 La mondialisation des échanges : quel rôle pour l'Afrique ?

L'augmentation de la consommation mondiale de produits aquatiques et la mise en place des grands marchés de consommation (Grand Marché européen de 1993, ouverture du marché des pays de l'Est), représentent pour les pays africains une chance à saisir dès maintenant (**cf. encadré 2**) ?

En effet, dans un environnement mondial où la compétition pour la commercialisation des produits halieutiques est de plus en plus vive, la concurrence des pêcheries du Sud-Est asiatique et de l'Amérique du Sud constitue un risque majeur pour les pêcheries africaines d'exportation, si celles-ci ne réagissent pas à temps pour se positionner sur les marchés extérieurs des pays du Nord. De plus, face à l'émergence des produits aquacoles et au réajustement de fait des cours des produits de la pêche, quel va être l'avenir de certaines pêcheries traditionnelles en compétition avec les produits d'élevage (cf. **encadré 3**) ?

La baisse de rentabilité des activités de pêche industrielle pour les pays les plus développés et la pleine exploitation des stocks halieutiques de leurs ZEE, ont conduit soit à leur désengagement vis-à-vis de leur flotte de pêche industrielle (modèle américain : vente de la flotte thonière à Taïwan) soit à une délocalisation de leur flotte dans des pays où les coûts

d'exploitation sont plus faibles (modèle européen : soutien au secteur des pêches européen à travers les subventions par achats de licences, mise en place de joint-ventures avec des pays tiers). L'aide de fait accordée à l'Afrique par la CEE dans l'exploitation de ses ressources hauturières s'inscrit dans une logique d'intérêt mutuel entre les deux parties (zones de pêche et main d'oeuvre des pays Africains, capital et immobilisations des pays européens). De plus, les liens historiques de coopération établis avec les pays européens, et en particulier la France, sont autant de facteurs qui devraient favoriser les échanges entre les deux continents. Face au danger que représentent les pays du Sud-Est asiatique, l'Afrique se doit de traiter avec l'Europe dans le cadre de l'aide au développement et ce d'autant plus que les accords ACP augmentent la compétitivité des produits halieutiques africains sur la marché européen (pas de prélèvements douaniers).

De plus l'apparition des biotechnologies, l'évolution rapide des nouveaux process et *in fine* des marchés (**encadré 4**) entraîneront des changements structurels considérables, auxquels les industries de la pêche ne devraient pas échapper. La sophistication des marchés dans les pays du Nord conduira à des difficultés croissantes pour l'accès des produits africains à ces marchés : apparition des labels de qualité, mise en place ou changement des normes, législations nationales restrictives (cf. **encadré 5**)... Dans cet environnement mondial évolutif, l'Afrique doit s'allier à des partenaires bien choisis pour éviter l'isolement économique.

### 3.2.2 La pression des écologistes occidentaux : une contrainte de plus en plus préoccupante

La montée des mouvements et pressions écologistes autrefois marginaux, prend de plus en plus de poids politique sur le plan national et international (cf. **encadré 6**). Cette nouvelle tendance doit être prise en compte sous ses différentes formes d'expression :

Tout d'abord, le discours écologique trop souvent passionnel et de surcroît porté par les opinions publiques occidentales, pèse lourd auprès des décideurs politiques qui sont contraints d'intégrer cette dimension dans leur choix. Cependant, les données écologiques sont parfois difficiles à prendre en considération de façon rationnelle et globale, d'une part parce qu'elles s'inscrivent dans un cadre dynamique et complexe où il est difficile d'avoir une démarche prospective, d'autre part parce que les problèmes et les priorités en matière d'écologie et de protection de l'environnement peuvent être très différentes d'un pays à l'autre, en fonction notamment du niveau de développement (cf. **encadré 7**).

Aujourd'hui, l'écologie devient également une "arme stratégique" utilisée par les industriels pour influencer et favoriser le développement de certains marchés (cf. **encadré 8**), et utilisée par les gouvernements comme mesure protectionniste (cf. **encadré 9**), souvent accompagnée de mesures discriminatoires à l'encontre de pays peu respectueux envers la Nature. Le danger, consiste surtout ici en des prises de positions "écologiques" irrationnelles et non scientifiquement fondées.

### 3.2.3 La déstructuration restructuration des pays de l'Est : quels risques pour l'Afrique ?

Les bouleversements survenus récemment dans les pays de l'Est ont entraîné une nouvelle donne sur la scène internationale des négociations : aujourd'hui, se posent un certain nombre de questions sur lesquelles nous devons engager une réflexion commune. En premier lieu, quel rôle vont jouer les partenaires traditionnels de l'Afrique et en particulier la CEE dans les années à venir : vont-ils privilégier des axes de coopération Nord-Sud ou Est-Ouest (cf. **encadré 10**) ? En particulier, dans le secteur des pêches, il est certain que les flottilles de l'Est ont des besoins d'aides importants, pour faire face à la mise en place de l'économie de marché (vérité des coûts, impératifs de rentabilité). Un arbitrage sera nécessaire entre les besoins d'aides réels des pays de l'Est et l'aide traditionnelle aux pays d'Afrique, dont les besoins ne cessent de croître. Pour le secteur des pêches, l'impact à terme de ces bouleversements est particulièrement difficile à évaluer, tant la mondialisation du secteur a développé des réseaux complexes d'accords et d'échanges (**encadré 11**).

Dans ce nouveau contexte, le redéploiement éventuel de la flotte de pêche hauturière russe ne pourrait s'opérer qu'en tenant compte des contraintes d'exploitation des stocks halieutiques mondiaux (sur quelles zones et sur quelles espèces), et des contraintes socio-économiques dans les pays de l'Est (coût de restructuration de la flotte, chute du niveau de vie et de la production globale, problème de solvabilité à terme...). En particulier, les pays de l'Est pourront-ils continuer à exploiter les stocks hauturiers des ZEE africaines, et garder leurs liens traditionnels avec leurs partenaires africains ?

Ce brutal bouleversement des données d'exploitation par les flottilles des pays de l'Est aura des répercussions à la fois économiques chez leurs partenaires traditionnels et écologiques sur les stocks précédemment exploités. Aujourd'hui, sur

quelles bases et à qui accorder de nouveaux droits de pêche en remplacement de l'exploitation soviétique ? Faut-il, en définitive, accorder de nouveaux droits sur les anciens stocks exploités par les pays de l'Est, ou l'Afrique doit-elle les exploiter par elle-même ?

En plus de ces données mondiales qui ne vont pas manquer d'influencer notablement le secteur des pêches en Afrique, il faut également prendre en compte les caractéristiques propres du continent africain, concernant bien sûr le secteur des pêches mais aussi son environnement social, économique et politique.

## 4. LES STRATEGIES DE DEVELOPPEMENT PROPOSEES

La question est simple : quel doit être la destination des pêches africaines (apport nutritionnel, devises) et par qui les ressources doivent-elles être exploitées (flottes étrangères, flottes nationales, industrielles ou artisanales) ?

Pour ce qui est du premier point, une constatation s'impose : mis à part les stocks "libérés" par les flottille de l'Est, la production halieutique africaine n'a guère de chances d'augmenter. On pourrait envisager différentes solutions pour satisfaire les besoins nutritionnels de l'Afrique :

i) *Développer l'aquaculture.* Cette solution, telle qu'appliquée actuellement, ne semble pas capable de fournir une quantité de poisson suffisante, n'ayant jamais montré de développement satisfaisant. Par contre, l'aquaculture "extensive" d'aménagement à grande échelle des plans d'eau (acadjas du Bénin) serait à même de fournir des quantités bien plus importantes. Il faut donc réorienter les politiques de développement aquacole.

ii) *S'approprier les ressources exploitées actuellement par les flottes étrangères.* Cette solution ne peut être sérieusement envisagée dans le court terme car la majorité des pays africains ne peuvent se permettre d'investir dans une flotte industrielle extrêmement coûteuse, et de rentabilité marginale. Part contre, dans le cadre d'accords de pêche, de joint ventures... il est tout à fait envisageable et normal que les pays africains s'approprient une part de cette ressource, que se soit en nature ou en devises.

iii) *Exploiter les stocks de pélagiques côtiers auparavant pêchés par les flottille de l'Est.* Il existe là une possibilité, ces stocks de faible valeur monétaire pouvant facilement trouver des débouchés en Afrique et n'intéressant pas les pays développés. Pour les mêmes raisons que précédemment cette exploitation ne pourrait être raisonnablement être faite de façon industrielle et devra donc faire l'objet du développement d'un nouveau créneau de pêche artisanale, là où cela est techniquement possible. Compte tenu des coûts d'exploitation (en particulier vérité des coûts pour les flottilles de l'Est) et de la valeur marchande de ces poissons, il est extrêmement peu probable qu'ils soient exploitables à court terme par des flottes industrielles, africaines ou étrangères.

iv) *Augmenter les importations.* Cette solution qui ne se heurte pas directement à un problème de ressource (disponibilité sur le marché mondial de grandes quantités de poisson congelé de faible valeur monétaire) est actuellement limitée par la pénurie en devises et les politiques d'ajustement structurel.

Ceci nous amène au deuxième niveau où le secteur des pêches peut avoir un intérêt : celui de l'apport en devises. En effet, compte tenu de la limitation en volume des captures, la solution qui s'impose est de rechercher une valorisation maximale pour retirer le meilleur parti de la production halieutique. Là encore, plusieurs solution sont possibles :

i) *Tirer le meilleur parti des accords de pêche et lutter contre les pêches illicites.* Ceci nécessite une coopération entre Etats africains, un renforcement du cadre administratif, pour négocier les accords sur des bases solides et avoir les moyens de contrôler les pêches illégales, qu'aucun Etat n'a les moyens de se procurer seul.

ii) *Valoriser au mieux les différents types de poissons pêchés en Afrique.* Il faut pour cela tenir compte des marchés existants, de leur solvabilité et de leurs demandes. Par exemple, la pêche artisanale africaine produits une part importante d'espèces dont la valeur sur les marchés occidentaux est élevée. Leur exportation pourrait être une source notable de devises, mais ne pourrait se faire efficacement que part des accords de type joint venture avec des partenaires privés connaissant ces marchés, leurs contraintes (normes...) et disposant des infrastructures nécessaires à la commercialisation du poisson dans les meilleurs conditions. Des espèces de moindre valeur

pourraient être commercialisées sur les marchés intra-africains, mais encore faudrait-il une connaissance réciproque des besoins et des disponibilités ainsi qu'une amélioration des infrastructures de communication. Enfin, les espèces de faibles valeurs pourraient être commercialisées directement sur les marchés locaux, par des circuits courts (sans chaîne du froid) permettant de maintenir des prix bas sur ces marchés à faible pouvoir d'achat.

iii) *Développer l'exportation de produits aquacoles de luxe.* L'Afrique dispose de nombreux sites aquacoles potentiels et d'une main d'oeuvre bon marché. Elle a déjà développée (Zimbabwe) un élevage de crocodiles fournissant des peaux de haute valeur marchande sur le marché mondial. Par contre, l'aquaculture de crevettes, en explosion en Amérique du Sud et dans les pays du Sud Est asiatique n'a pas encore décollé en Afrique, malgré quelques tentatives prometteuses (Madagascar). Les pêcheries étant menacées à terme par ce développement mondial de l'aquaculture, il faudra étudier les possibilités pour l'Afrique de se placer sur ce créneau, sans doute par le biais de joint ventures avec des partenaires étrangers détenant savoir-faire et circuit de commercialisation. A plus long terme, la limitation du volume des captures au niveau mondial induira également une recherche de valorisation maximale de toutes les espèces, déjà commencée avec des produits comme le surimi. Cette tendance qui devrait s'accentuer, pourra conduire à terme à la hausse des prix des espèces pélagiques et donner un avantage certain aux régions qui en disposent en grande quantité, telle l'Afrique.

Il y a de nombreuses voies possible pour développer les pêches et l'aquaculture africaines, soit dans le sens d'un meilleur apport nutritionnel, soit dans le sens de rentrées accrues de devises. Ces deux alternatives ne s'excluent pas l'une de l'autre, mais peuvent et doivent être complémentaires et effectuées conjointement sur des segments de production et de marché différents. Compte tenu des caractéristiques particulières de chaque pays il n'existe pas une solution idéale, mais pour chacun un équilibre à trouver et des pistes à explorer.

Cependant, des conditions indispensables à terme au développement du secteur sont d'abord l'adoption de politiques claires et réfléchies, la création d'un cadre propice à l'initiative, la mise en place de structures d'encadrement et de formation efficaces...

Ceci ne pourra se faire que dans le cadre d'une coopération accrue entre pays africains, mais aussi avec les pays non africains, cette coopération pouvant prendre un grand nombre de formes différentes mais devant toujours partir d'un intérêt mutuel ressenti par les différentes parties.

## 5. CONCLUSION ET RECOMMANDATIONS

Oui, il existe une place pour le secteur halieutique africain dans le cadre de la nouvelle donne mondiale.

Pour cela il faut :

**- maintenir et accroître les efforts de coopération à tous les niveaux :**

i) *favoriser le rapprochement entre Etats africains* présentant des caractéristiques communes (données géographiques communes/données politiques et économiques semblables...) pour établir des programmes et des actions conjointes dans le secteur des pêches et de l'aquaculture. Ceci devrait permettre de définir et d'expliciter clairement les objectifs nationaux pour le secteur des pêches, de renforcer ou mettre en place des capacités administratives, l'application des réglementations (harmonisation des législations pour l'exploitation des stocks partagés), la collecte et les échanges d'informations : bases de données sous régionales d'informations maritimes (ex : projet des 22 Etats africains riverains de l'Océan Atlantique), commission sous régionale (ex : COI), colloques, séminaires, programmes universitaires communs, programmes scientifiques conjoints... (cf. **encadré 12**). Ceci devrait aboutir à terme à une intégration sous-régionale entre pays ayant des besoins comparables ou complémentaires. Ceci devrait permettre des économies d'échelle et des réalisations communes dans le cadre de structures de négociation, de recherche, d'enseignement, voire même à terme de production (flottes communes sous forme de joint-ventures permettant une exploitation des stocks non pêchables artisanalement).

ii) *coopération avec les pays tiers traditionnellement partenaires de l'Afrique,* en particulier l'Europe. Etablissement de joint-ventures, accord de droits et de licences de pêche avec les pays possédant des flottes de

pêche industrielle pour permettre l'exploitation des stocks hauturiers (cf. **encadré 13**). Eviter tout développement inutile de flottes de pêche industrielle nationales dans des pays où les coûts d'opportunité sont souvent élevés et le capital rare. Ce partenariat avec les pays du Nord est également indispensable pour la commercialisation des produits et pour assurer une veille à l'évolution des marchés.

**-Favoriser le développement du monde rural et avec lui, celui du secteur artisanal :**

Promouvoir la mise en route de nouveaux projets en mettant l'accent sur les opérateurs réels, surtout ceux du monde rural qui sont à terme les seuls garants d'un développement économique durable en Afrique. Ceci doit correspondre à un choix politique délibéré accordant une large place à la composante sociale. Dans le domaine des pêches, si, sur les mêmes ressources, la pêche artisanale est plus compétitive que la pêche industrielle, il reste que cette dernière est la seule à pouvoir exploiter certains stocks (ex : stocks hauturiers) et ne doit en conséquence ne pas être abandonnée. Il faudra donc favoriser, *lorsque ceci est possible*, le développement de la pêche artisanale à travers trois volets :

i) Face aux contraintes de niveau d'exploitation, la seule voie possible pour accroître la richesse potentielle extraite des ressources halieutiques consiste *en une maximisation de la valorisation des espèces pêchées.* La commercialisation des produits de la pêche artisanale sur les marchés extérieurs du Nord est pour les espèces nobles le meilleur moyen de maximiser cette valorisation. Cette action procède d'une double constatation. D'une part, elle répond à l'intérêt grandissant envers ces produits, de la part des divers intervenants du secteur pêche des pays du Nord, préoccupés par l'augmentation et par la diversification de leurs sources d'approvisionnement face à un marché européen dont la demande en produits de la mer est croissante et la production stationnaire. D'autre part, elle répond également à l'intérêt des pays africains qui peuvent valoriser une part de leurs ressources halieutiques de très bonne qualité par le biais d'exportations payables en devises fortes sur des marchés demandeurs et riches (cf. **encadré 14** ). Dans ce cadre et tenant compte de la sensibilité "écologique", l'image d'un produit "artisanal" et exotique pourra être pleinement valorisée, pour peu qu'il rentre dans les normes de qualité.

C'est à travers des structures conjointes (joint venture), de partenariat (investissement d'entreprises privées en Afrique et opérateurs africains) que cette commercialisation doit se concrétiser, car de telles structures favorisent, d'une part, la rencontre entre l'offre des producteurs africains et la demande des marchés du Nord, et d'autre part elles permettent les financements notamment en infrastructures indispensables à la commercialisation de produits de qualité (packaging, logistique de transport...). Elles permettent enfin d'assurer la création d'emplois dans le pays hôte, un transfert de savoir-faire et une veille à l'évolution de la demande des grands marchés du Nord (évolution des contextes normatifs, et législatifs, évolution des grandes tendances de consommation) (cf. **encadré 15).** ). Le pays hôte, quant à lui, à travers ses opérateurs, garantit l'accès aux circuits de production et de vente par sa connaissance du terrain, des acteurs de la filière et des spécificités culturelles liées au pays.

Cette commercialisation ne peut néanmoins se concevoir sans des études de marchés précises et des efforts de promotion pour positionner les produits de la pêche artisanale africaine sur un ou des segments de marchés adaptés au pays du Nord. Il faut privilégier le développement des productions artisanales, pratiquement seules à fournir un tel niveau de qualité, de diversité des produits et génératrice d'un nombre d'emplois potentiels en Afrique bien supérieure à ce que l'on peut espérer de la pêche industrielle. Ceci implique également la mise en place de conditions nécessaires au montage de sociétés mixtes et à l'investissement de capitaux étrangers en Afrique : mesures fiscales favorables à l'investissement étranger et aux opérateurs africains (cf. **encadré 16**), accès au crédit pour ces derniers, un niveau de développement minimum assurant un environnement favorable à l'initiative privée et favorisant la concurrence.

ii) *le deuxième volet de développement de la production artisanale se situe sur le plan des marchés intra-africains* dont certains sont fortement demandeurs (Nigéria, Côte d'Ivoire, Zaïre, Angola et Cameroun, ces cinq pays concentrant à eux seuls 59 % des quantités de poissons importées en Afrique). La plus grande part de la demande africaine est satisfaite par des importations de poissons de faible valeur comme les petits pélagiques. Certaines pêcheries artisanales pourraient trouver un créneau en remplacement de l'exploitation soviétique sur des stocks de petits pélagiques côtiers. Ceci permettrait en outre de restituer en partie l'équilibre des apports alimentaires de petits pélagiques dont les débarquements en Afrique par la flotte Russe ont été interrompus. De plus, l'exploitation de tels stocks par des unités de pêche artisanale pourrait être valorisée à travers un pool de transformation, à condition toutefois que les apports de la flotte soient suffisamment réguliers et importants. A l'heure actuelle, la technique de conservation par appertisation, sur ce type de ressources, semble la plus rentable et la mieux adaptée aux contraintes de commercialisation sur le territoire africain. Dans le cadre d'échanges intra-africains une coopération entre les pays est nécessaire afin de mettre en place des règles douanières concertées, d'effectuer des études de marchés, des études de complémentarités...

iii) *le troisième volet enfin, concerne les productions artisanales peu ou pas exportables vers les pays du Nord et vers les pays africains.* Ces productions doivent trouver quant à elles des débouchés sur les marchés locaux. Dans tous les cas les circuits de distribution doivent être courts et sans surcoûts qui grèvent les marges et ne peuvent être de toute façon supportés par le consommateur final (en particulier éviter les chaînes de froid et les entrepôts frigorifiques qui sont des investissements trop coûteux). Là encore le développement des échanges ne peut se faire que dans le cadre d'un système qui soit en compétition réelle, en évitant la mise en place de tous monopoles, en particulier ceux induits par les coopératives sous contrôle de l'Etat, et en réduisant enfin l'intervention étatique à sa stricte nécessité.

Concernant l'amont du secteur, il convient de rappeler que l'aménagement de la pêche artisanale doit s'effectuer par le contrôle de l'accès à la ressource afin de ne pas accroître la pression d'exploitation sur les stocks. Il faut pouvoir réguler l'effort de pêche afin d'accroître le revenu des pêcheurs, leur pouvoir d'achat et non leurs effectifs. Pour ce faire, il est nécessaire de porter une attention particulière aux systèmes coutumiers de droits territoriaux qui représentent une bonne base d'aménagement des pêcheries artisanales dispersées et éloignées (gestion déléguée aux communautés de pêcheurs) et réduisent également le coût de la surveillance. Enfin, il est nécessaire de réguler l'entrée dans certaines pêcheries, mais ceci ne pourra se faire que dans un contexte de croissance démographique maîtrisée et de développement de l'emploi dans d'autres secteurs.

**- Réorienter les politiques de développement aquacole.**

Face à l'échec enregistré depuis trente ans dans le développement de la pisciculture "rurale" de tilapias, et vu les défis posés à l'Afrique en terme de besoins nutritionnels, de concurrence mondiale sur certains produits (crevettes) et de besoins en devises, il faut réorienter le développement aquacole en Afrique selon deux voies principales :

i) *une voie à dominante "nutritionnelle"* par aménagement extensif sur des zones étendues (types acadjas au Bénin, qui devrait permettre la production d'une grande quantité de poisson à faible coût, et en même temps créer des emplois et une élévation du niveau de vie.

ii) *une voie à dominante "exportation"* portant sur des produits de hautes valeur telle que la crevette ou le crocodile. La production de peaux de crocodiles, déjà effective dans certains pays (Zimbabwe) semble particulièrement prometteuse. La production de crevette semble également intéressante dans certains pays (Madagascar), et, à terme, nombre de sites aquacoles potentiels représentera certainement un avantage pour l'Afrique, face aux grandes concentrations et aux risques, en particulier pathologiques, qui en découlent en Amérique du Sud ou en Asie du Sud Est.

Toutes ces recommandations doivent être assumées et soutenues, non seulement par les pays africains, mais aussi par leurs partenaires du Nord, dont l'intérêt ultime reste un développement équilibré de l'Afrique, sous peine de supporter le coût exorbitant d'un "mal développement" de ce continent (immigration massive, augmentation des aides alimentaires et de diverses formes à fonds perdus). C'est à travers cette philosophie, à un stade de réflexion amont et globale que la CEA, quant à elle, entend exercer ses compétences.

**Encadré 1** : sources FAO

| | 1980 | 1989 |
|---|---|---|
| Exportations africaines (US$ constants) : | 122 000 millions | 81 500 millions |
| Exportations agricoles (US$ constants) : | 14 200 millions | 12 200 millions |
| Exportations halieutiques (US$ constants) : | 500 millions | 1 500 millions |

Solde commercial du secteur halieutique en 1989 : + 600 millions US$

**Encadré 2** : source INFOFISH INTERNATIONAL jan-fev/90 et sept-oct/90

Mise en place des grands marchés de consommation

En 1992, avec l'abolition des particularités réglementaires nationales grâce à la mise en place du **Marché Unique de la CEE**, les exportateurs de produits aquatiques auront un marché de **320 millions de consommateurs** à leur portée. La volonté de créer un **"Espace Economique Européen" (CEE + AELE Association Européenne de Libre Echange)** porterait le marché à **355 millions d'habitants**. Les changements politiques récents en Europe de l'Est avec l'ouverture vers l'économie de marché vont faciliter les échanges commerciaux avec 137 millions d'habitants. Si on ajoute **283 millions de soviétiques**, ce serait un marché de **770 millions de personnes dans une Europe entièrement unifiée. Ce marché est évalué à 21 millions de tonnes de produits aquatiques.**

**Encadré 3** :

Nous citons ici des exemples illustrants la substitution ou la compétition entre certains produits de la pêche et les produits d'élevage :

Le Saumon d'élevage a entraîné la disparition de certaines pêcheries des Iles Féroé et du Groënland spécialisées dans ce poisson. D'une manière générale, comme pour le Saumon, l'aquaculture des crevettes Pénéïdes risque de mettre en péril bien des pêcheries de pays en développement, notamment celles de petite envergure sur le plan des tonnages, même si leur rôle économique est primordial : première source de devises pour Madagascar, que représentent 6000 tonnes de crevettes face aux centaines de milliers de tonnes produites maintenant par l'aquaculture ?

Quel impact auront l'élevage du Coryphène mahimahi (Coryphanae hippurus) et des Thonidés sur les pêcheries tropicales lorsque leur technique d'élevage seront au point ?

**Encadré 4** :

En 1984, une société malgache, la S.M.E.F., lance une étude de marché pour la chair du Crabe des mangroves (Scylla serrata) en France. L'existence d'un créneau pour plusieurs milliers de tonnes de produits est ainsi mis en évidence (800 à 900 Tonnes). Lorsqu'en 1988 la société lance son produit sur le marché, celui-ci a été réduit à quelques centaines de tonnes (300 Tonnes). Pourquoi ? Parce qu'entre temps, les japonais se sont lancés dans l'exportation du surimi au goût de crabe produit à partir du lieu des îles Aléoutiennes (Alaska pollack).

CEE : les importations de produits de la mer doivent se conformer aux normes européennes

La CEE a approuvé deux Directives pour l'adoption par les pays membres. **La Directive fixant les règles sanitaires régissant les produits de la pêche et une autre s'appliquant aux mollusques bivalves vivants** veulent que les pays exportateurs s'assurent que **les normes sanitaires des produits de la pêche exportés vers la CEE soient "au moins équivalentes" à celles des produits en Europe**... Des exigences générales sont prévues pour les navires usines, la manutention et la transformation, l'inspection des produits, l'emballage, le marquage et l'entreposage, le stockage et le transport... Les pays exportateurs peuvent se concerter avec la CEE en vue de l'établissement des conditions spécifiques d'importation et des inspections sur place par la CEE. **Les Etats membres de la CEE devraient faire appliquer les Directives avant janvier 1993.**

Nations Unies : résolution pour mettre fin à la pêche aux filets dérivants.

Le deuxième comité (affaires économiques) de l'Assemblée des Nations Unies a adopté le 6 décembre 1991 une résolution interdisant la pêche aux grands filets dérivants en haute mer par consensus de tous les pays participants. La résolution comprend deux parties :

i) les captures par les grands filets dérivants seront réduites par moitié, d'ici juin 1992,

ii) d'ici fin décembre 1992, il y aura un moratoire global sur la pêche aux filets dérivants. Le 20 décembre, l'Assemblée générale de l'ONU a adopté à l'unanimité la résolution qui a été conjointement proposée par 31 pays, sans vote.

**Encadré 7 :** Source RESUME ANALYTIQUE DES QUESTIONS DONT A ETE SAISIE LA DIX-HUITIEME CONFERENCE DES MINISTRES AFRICAINS 20/04/92

Dans le domaine de l'environnement, la Conférence des Nations Unies sur l'environnement et le développement s'est tenue à Rio de Janeiro (Brésil) en juin 1993. La position africaine a été élaborée lors de la réunion ministérielle tenue au Caire du 11 au 16 juillet 1991 et de la réunion complémentaire tenue à Abidjan du 11 au 14 novembre 1991. Il existe une différence entre la Conférence de Stockholm (1972) et celle de Rio. En 1972, on pouvait constater une intention affirmée d'élaborer des solutions écologiques aux problèmes causés par le développement. Les "méchants" étaient clairement identifiés : industries polluantes, moteurs à essence inefficaces, agriculteurs et bûcherons à la négligence criminelle. Les "bons" seraient les organismes à vocation écologique qui, nantis de pouvoir juridiques appropriés, mettraient hors d'état de nuire les ennemis d'un environnement sain. Le problème était perçu sous l'angle des pays développés : la dégradation de l'environnement était un moyen de réduire les coûts de production et de fonctionnement. Vingt ans après, **les pays en développement perçoivent les problèmes d'environnement sous un angle beaucoup moins simple. La dégradation de l'environnement résulte en effet de la pauvreté et seul le développement durable peut apporter des solutions. En Afrique, la pollution industrielle représente un faible pourcentage de la dégradation de l'environnement : les principaux problèmes sont la désertification, le déboisement et la pollution des eaux dans les zones pauvres et surpeuplées. Les acteurs les mieux placés pour résoudre ces problèmes ne sont plus les organismes écologiques traditionnellement orientés vers la lutte contre la pollution, mais plutôt les organismes de développement eux-mêmes. Cette manière de voir est aujourd'hui largement partagée.**

A la suite des pressions écologiques américaines **pour la protection des dauphins** qui sont capturés dans les sennes coulissantes avec les thons dans l'Océan Pacifique (dans cette zone les deux espèces occupent les mêmes niveaux trophiques), **des industriels de la conserverie de thonidés (Starkist) de la côte Ouest ont délocalisé leur industrie vers le Sud Est asiatique** où les captures de thons se font sans prise de dauphin. L'utilisation des lobbies américaines a permis de cautionner ce redéploiement **sous couvert de protection de l'environnement** "nous n'achèterons plus que des thons capturés sans dauphin". **La réalité : les coûts de main d'oeuvre nettement plus faibles pour l'industrie de la conserve en Asie du Sud Est, le chômage pour les ouvriers de la conserverie sur la côte Ouest américaine...**

**Encadré 9** : source INFOPECHE 22/02/92

Etats-Unis : interdiction d'importation de tout thon albacore

**Une cour fédérale a ordonné au gouvernement américain d'interdire toute importation de thon albacore des pays qui importent et ré-exportent vers les E-U**. Selon Reuter, le Département Américain des Douanes a imposé cette **ordonnance de la Cour de justice à 20 nations qui traitent le thon capturé à la senne coulissante, une technique préjudiciable aux dauphins**. Les vingt nations visées seraient la Grande Bretagne, le Canada, la Colombie, le Costa Rica, l'Equateur, la France, l'Indonésie, l'Italie, le Japon, la Corée du Sud, la Malaisie, les Iles Marshall, les Antilles Néerlandaises, le Panama, Singapour, l'Espagne, Taïwan, Thaïlande, Trinidad et Tobago et le Vénézuéla. Le Earth Island Institute de Californie responsable de cette injonction a rapporté que l'institut est convaincu que la Thaïlande se conforme aux normes "Dolphin safe" des autorités américaines et que la pénaliser elle et d'autres nations se déclarant "Dolphin safe" ne ferait que leur créer des difficultés.

**Encadré 10** : source INFOPECHE 22/05/92

Norvège : participation à des investissements en Russie

La province du Finmark dans l'extrême Nord de la Norvège a reçu du gouvernement norvégien 5 millions de couronnes en vue de sa participation à des investissements dans la province russe d'Arkangelsic, sur la mer blanche. **L'éclatement de l'Union Soviétique offre aux Norvégiens du Nord de grandes opportunités, notamment dans la mer de Barents.**

**Encadré 11** : source INFOPECHE 22/02/92

Ecosse/Afrique : les Klondykers veulent diversifier vers l'Afrique

Depuis que les grands congélateurs soviétiques et l'Allemagne de l'Est n'écoulent plus la production de maquereaux, ce produit n'est plus rentable pour les Klondykers écossais. Les armements tentent dorénavant de diversifier leurs contacts avec d'autres pays importateurs : l'Egypte, les pays du golfe de Guinée et les pays de l'Est. D'autre part, ils ont demandé que leur production soit prise en charge par le Gouvernement britannique et incluse dans les aides alimentaires en direction de la Russie.

**Encadré 12** : source INFOPECHE 07/03/92

Ghana/Namibie : coopération en matière de pêche

Le Ghana et la Namibie ont signé le 5 février 1992 un **accord visant à la création d'une Commission permanente mixte de coopération. L'objectif est de promouvoir la coopération entre les deux pays dans les domaines de la pêche, de la formation, du commerce et des mines.**

**Encadré 13** : source INFOPECHE 07/05/92

Namibie/Norvège : développement de la coopération halieutique

Suite un **accord bilatéral** signé en septembre 1991 entre la Norvège et la Namibie, les deux pays développent leur coopération en matière de pêche. **La coopération en 1991-1992 porte, entre autres, sur une assistance pour la surveillance de la pêche, la recherche sur l'environnement et les ressources halieutiques, le développement institutionnel et l'assistance technique. Pour 1992-93, la coopération concerne l'achat de navires de patrouille, une formation de haut niveau pour la recherche marine et la création d'un centre de recherche**. Un don de 1,2 millions de rands est également prévu pour 1992-93.

**Encadré 14** : source INFOPECHE 07/04/92

Kenya : percée de la perche du Nil sur le marché français

**Des perspectives prometteuses pour la perche du Nil en France**. Il y a trois ans, ce poisson était pratiquement inconnu en France. Mais actuellement **les filets congelés de perche du Nil sont activement commercialisés en France et sont très appréciés par les consommateurs**. Le Kenya fournit 90 % des importations françaises et l'Ouganda les 10 % restants. La demande émane principalement des collectivités mais aussi des magasins spécialisés dans la vente des produits surgelés. **Malgré les exigences strictes et les normes élevées du marché, la perche du Nil se taille graduellement mais sûrement un créneau sur les marchés européens. Cependant, pour assurer une expansion de sa part de marché, les campagnes promotionnelles ciblant les consommateurs, acheteurs institutionnels et restaurateurs doivent être entreprises, l'hygiène assurée au maximum dans les ateliers de filetage, la congélation et le stockage effectués selon les normes les plus élevées**.

**Encadré 15** : source INFOPECHE 22/03/92

Guinée : du poisson par avion de Conakry à Paris.

Depuis la fin de 1989, à raison de deux ou trois opérations par semaine, Soguipêche, la filiale de **la société française Jégo-Quéré, met du poisson de pirogue, en général 8 tonnes en caissettes avec de la glace sur le vol régulier de Conakry à Paris**. Là, les colis sont pris en charge par le transporteur Tradimar et expédiés à Lorient, où Europêche, autre filiale de Jégo-Quéré, les met à la disposition des acheteurs. **Sont ainsi proposés dorade, barracuda, carpe rouge, sole et thiof**. Les Dorades intéressent beaucoup les mareyeurs, cette espèce s'étant raréfiée en Europe. En 1991, le poisson de Conakry a représenté 162 tonnes à la criée de Kéroman, pour une valeur de 5,5 millions de francs. **Le développement du pôle guinéen devrait permettre de réaliser des expéditions de 20 à 23 tonnes par voyage**.

**Encadré 16** : source INFOPECHE 07/06/92

Sénégal : exonération douanière pour produits de la pêche

**L'exonération du timbre douanier** est désormais exclusivement réservée aux produits importés par les opérateurs économiques du secteur de la pêche, et utilisés comme intrants dans la production effectivement exportée, rapporte les "Marchés tropicaux". D'après le Conseil National du Patronat du Sénégal (CNP), **cette mesure s'insère dans le cadre du plan de relance de la pêche, secteur essentiellement tourné vers l'exportation**.

TABLEAU 1.
CHIFFRES CLES DU SECTEUR HALIEUTIQUE AFRICAIN (SOURCE FAO 1988-1989).

## I PRODUCTION

**Production halieutique (tonnes)** : 7 800 000

. Eaux continentales : 1 300 000
. Eaux marines production africaine : 3 200 000
. Eaux marines production étrangère : 3 300 000

**Production aquacole (tonnes)** : 110 000
**2/3 produites par l'Egypte**

**Principaux pays producteurs** : 70 % de la production totale

. Afrique du Sud
. Maroc
. Ghana
. Tanzanie
. Nigéria
. Sénégal
. Egypte
. Ouganda
. Zaïre

**Nombre de navires** : 7 600
**Nombre de pirogues** : 355 000

## II EMPLOI

**Nombre de pêcheurs** : 2 millions
**Nombre d'emplois induits** : 8 millions

**Total** : 10 millions

10 millions qui représentent 9 % de la population active totale du secteur agricole.

## III COMMERCE EXTERIEUR

Exportations (millions US $) : 1 500
Importations (millions US $) : 900

Solde (millions US $) : + 600

**Principaux pays exportateurs :** 83 % des exportations en valeur

| | |
|---|---|
| . Maroc | . Côte d'ivoire |
| . Sénégal | . Afrique du Sud |
| . Mauritanie | . Tunisie |

**Principaux pays importateurs :** 77 % des importations en valeur

| | |
|---|---|
| . Egypte | . Zaïre |
| . Côte d'Ivoire | . Afrique du Sud |
| . Nigéria | . Cameroun |
| . Angola | . Algérie |

## IV CONSOMMATION

**Offre moyenne en poisson :** 7,9 kg/hab/an en 1989

Pour maintenir ce niveau d'offre les approvisionnements (production + importations) devront croître de 50 000 tonnes par ans.

# Problématiques du Développement des Pêches

**Jacques Weber**

IFREMER/DRV, Technopolis 40, 155 rue J.J. Rousseau, 92238 Issy Les Moulineaux, FRANCE

RÉSUMÉ

*Depuis trente deux ans, le "développement", dans les pêches comme en agriculture, est fondé sur des "projets" dont le taux de réussite est très faible en dépit de la qualité de leur conception et des experts qui en ont eu la charge. Pendant la même période et dans les mêmes secteurs, de multiples réussites techniques, économiques et sociales sont observables, qui ont en commun, sauf exception, de n'avoir aucun lien avec les projets de développement. Et si la longue litanie des échecs trouvait son origine dans la notion même de "projet de développement" ? L'opinion personnelle avancée ici est que la solution ne réside pas dans l'amélioration des projets, mais peut-être bien dans leur suppression, comme condition nécessaire du développement halieutique et agricole dans les PVD. La mise en oeuvre d'une innovation est un processus d'appropriation sociale, qui ne peut être initié de l'extérieur ; il est par contre possible de repérer des évolutions déjà entamées et de contribuer à leur accélération. Ceci ne nécessite ni structure de projet, ni bureaucratie, mais implique une révision profonde des doctrines des organisations internationales et bancaires.*

ABSTRACT

*For 32 years, "development" in fisheries or agriculture has been based upon "projects" the effectiveness of which has been very low, despite the quality of their conception and of the experts in charge of these projects. Meanwhile and at the same place, a lot of technical, economic and social successes can be observed, which have usually in common the fact of having no relationship at all with development projects. Why would not all these failures be rooted in the very notion of "development project" ? The personal opinion presented here is that the solution is not in improving the projects but perhaps in their suppression, a necessary condition for development of fisheries and agriculture in developing countries. The implementation of an innovation is a process of social appropriation which can not be initiated from outside ; on the contrary, it is possible to point out starting evolutions and to contribute to their speeding up. That requires neither project structure, nor bureaucracy but implies a deep revision in the way of thinking among international and financial organizations.*

## 1. INTRODUCTION

Il existe pas une mais des pêches artisanales, des problématiques, des développements. L'approche la plus répandue consiste à décrire des situations en recherchant ce qu'elles ont en *commun* , leur plus petit commun dénominateur, puis à baser une analyse générale sur ce denominateur commun. Il est proposé de chercher explicitement ce que les situations ont de *différent,* et ce que ces différences nous disent à la fois sur les pêches artisanales et sur le développement. Il ne s'agit pas d'une invitation à sombrer dans le relativisme et l'idée que tout étant spécifique, il n'y aurait aucune perspective générale à dégager !

Lorsqu'on parle de "développement", ce sont les *projets* qui nous viennent en tête. Il convient donc de rappeler qu'on entend par *développement* "un processus cumulatif de croissance auto-entretenu", non un projet ou son absence. En assimilant plus ou moins consciemment le développement et les projets de développement, il est aisé de conclure à une répétition d'échecs. la difficulté de trouver des *success stories...* Pourtant, il existe bien des exemples de dynamiques de développement ayant nécessité ou entraîné des modifications profondes du système pêche, ceci sans la présence de projets de développement.

Il n'y a pas une mais *des* pêches artisanales et/ou industrielles, avec des développements forts différents d'un pays à un autre ; qu'il y a donc *des* problématiques de développement des pêches.

## 2. DES DÉVELOPPEMENTS RÉUSSIS

### *2.1. Le développement d'une pêcherie de céphalopodes au Sénégal*

A la fin des années soixante-dix, les industries japonaises diffusent du matériel de pêche adapté à la seiche parmi les pêcheurs artisans du Sénégal et organisent un circuit de collecte des débarquements de cette espèce. La technique se répand rapidement (turlutte, casiers) sur la Petite Côte du Sénégal, permettant l'avènement d'une pêcherie saisonnière spécialisée débarquant jusqu'à dix mille tonnes de céphalopodes par an, dans les années quatre-vingt.

Aucun "projet de développement" ne se trouve derrière ce développement mais une industrie qui génère ses approvisionnements en fournissant matériels de pêche et prix rémunérateurs ; une recherche qui *accompagne* ce développement par la localisation et le suivi des ressources comme par l'amélioration des techniques de pêche (Bakayoko, 1989). Pour finir, si les bateaux industriels permettent dans un premier temps la localisation des lieux de pêche par les artisans, c'est l'inverse qui est observable après quelques années, lorsque les pêcheurs piroguiers ont appris à connaître leur espèce-cible.

### *2.2. L'association crevettiers-piroguiers*

Chacun sait que la pêche crevettière rejette une part très importante de ses captures, y compris les espèces nobles. Au Sénégal, au début des années quatre-vingt, des pêchers piroguiers associés avec les crevettiers, récupéraient une partie de ces rejets pour les commercialiser dans les points de débarquement de la pêche artisanale. Cette association s'observait également avec certains chalutiers.

L'intérêt de ce genre d'association est multiple : outre qu'elle transforme les habituels conflits entre industriels et artisans en copération, elle valorise les rejets et allège d'autant l'effort de pêche des piroguiers tout en assurant un revenu avec faible coût de production.

Ce genre d'association n'est, à ma connaissance, suivi ni par la recherche, ni par les administrations, au-delà d'éventuelles déclarations. Or si ces associations sont "bonnes" dans leur principe, elles peuvent donner lieu à toutes sortes d'effets pervers, en l'absence de contrôle.

Enfin, il n'y a pas de "projet de développement " derrière ces associations.

On retrouve ce type d'asociation entre piroguiers et navires hauturiers, qui emmènent pirogues et pêcheurs sur des hauts fonds qui leur seraient inaccessibles, et achètent leurs captures.

*2.3. La diffusion des sennes tournantes au Sénégal*

En 1967, la recherche contribue, avec l'assistance de technologistes FAO, à la diffusion du Filet Maillant Encerclant (FME) sur la Petite Côte du Sénégal. Cet engin se diffuse sans gros changement dans l'outil de production, la pirogue de 14 mètres, et contribue à un accroissement de l'équipage : 7 marins contre 3 à 5 antérieurement.

Devant le succès de cet engin, il est envisagé de tenter la diffusion des Sennes tournantes et Coulissantes. Sur proposition de la recherche, la FAO met un technologiste *à la disposition* des pêcheurs, munis de nappes de filets et accessoires. C'est un dialogue quotidien entre ce technicien et les pêcheurs qui aboutit au modèle actuel de senne, de 300 m. de longueur et 30 mètres de chûte. Nous sommes en 1972-73 ; en 1980, 200 unités de senne tournante sont recensées ; elles seront 250 en 1983 et 391 en 1987 (SOCECO-PECHART, 1983 et 1988). Le succès de cet engin est total.

Une innovation *technique* est en fait un *processus social complexe.* Il ne s'agit pas que l'innovation soit *acceptée* ou *adaptée* , mais bel et bien qu'elle soit *appropriée par* les pêcheurs, qu'elle devienne leur propriété. Et cela implique une modification en profondeur de tout le système pêche concerné.

*Au niveau de la production* : l'outil passe de une pirogue à deux. L'une, de 14 mètres, porte la senne et opère la poursuite et l'encerclement du banc ; la seconde, de 18 à 25 mètres et d'une capacité pouvant aler jusqu'à 25 tonnes, transportera la capture. Dans un premier temps, cette grande pirogue provient du transport de coquillages et d'arachides sur le Saloum et la Gambie ; progressivement, elle sera construite spécifiquement pour la senne tournante. L'unité de pêche comprend en outre trois moteurs, deux de 25 ch., un de 40 ch. pour l'encerclement du banc. Entre le FME et la Senne Tournante, l'investissement initial est passé de 1,5 Millions CFA à 5 Millions CFA (données de 1983).

*Au niveau de l'emploi* : on passe de 7 à 14-16 marins embarqués. Ce qui suppose un effectif total de l'ordre de 24 à 25 personnes, pour tenir compte des repos, maladies et absences. Des paysans viennent s'embaucher sur ces unités de pêche qui, hormis le patron et son adjoint, ne nécessitent pas de connaissances particulières.

*L'innovation de la senne tournante conduit en fait à une unité de production entièrement nouvelle, tant par sa dimension que par sa structure en capital et en emploi.*

*La commercialisation.* Le mareyage ne pouvait pas absorber facilement un afflux important de poisson débarqué par les sennnes tournantes (80.000 tonnes par an environ). Si la commercialisation en frais avait été le seul débouché, les cours se seraient effondrés, des quantités importantes auraient été rejetées à la mer et, très vraissemblablement, les pêcheurs se seraient repliés sur les anciennes techniques de pêche. Certaines entreprises de mareyage se sont construites sur le développement de la senne tournante, puis ont acquis des unités de pêche : certains mareyeurs possèdent jusqu'à 12 unités de pêche, soit un personnel de l'ordre de 300 personnes...

*La transformation artisanale.* Au fur et à mesure du développement des sennes tournantes, les femmes ont développé à grande échelle le braisage des poissons pélagiques. La technique est ancienne, mais portait avant cela sur des quantités peu importantes de matière première. Ce développement sans précédent de la transformation artisanale aura des conséquences multiples :

- les femmes se posent en concurrentes des mareyeurs et assurent un prix plancher au débarquement
- par la transformation qui permet une conservation du produit, elles permettent une relative régularisation du marché
- l'importance des débarquements permet à des femmes de l'intérieur du pays de venir s'adonner à cette activité en morte-saison agricole

*Au total, c'est un nouveau système pêche qui se met en place, pour donner plein effet à une innovation technique particulière.*

Il convient de remarquer que dans ce processus endogène de développement n'intervient aucun projet de développement spécifique. Mais que l'innovation bénéficie d'une conjonction de facteurs favorables qui *l'accompagnent* :

- la motorisation des pirogues était indispensable : le projet motorisation des pirogues y avait pourvu
- la recherche a accompagné le processus en permanence et dès le début
- la possibilité d'acheter moteurs et filets à crédit à été déterminante.

Ainsi, il existe bien des *"success stories"* . Elles ont en commun d'être le fait des pêcheurs eux-mêmes, qui s'approprient une innovation et, à partir de là, modifient s'il le faut l'ensemble du système-pêche. C'est, me semble-t-il, la grande leçon qu'il nous faut retenir : aussi longtemps que les pêcheurs ne s'approprient pas une innovation, à partir de critères qui sont essentiellement sociaux, cette innovation ne peut être imposée de l'extérieur du système. Par contre, une innovation n'est pas acceptée en raison de sa simplicité ou de sa complexité, mais bien de son appropriabilité, laquelle n'est pas affaire de complexité technique, mais de compatibilité sociale. Le caractère social de l'innovation conduit à prendre conscience également que l'innovation ne peut pas être le fait d'un individu isolé.

## 3. QUELQUES PROJETS DE DEVELOPPEMENT

### *3.1. Les coopératives*

Un peu partout en Afrique, les projets de développement ont cherché à susciter la création de coopératives sur lesquelles ils pourraient s'appuyer. La première fonction de ces coopératives étant de fournir une caution solidaire pour la seconde fonction qui est l'accès au crédit et la troisième fonction qui consiste en la distribution de matériels de pêche. A ces trois fonctions vient souvent s'ajouter une quatrième, la commercialisation.

Ainsi les coopératives devraient être à la fois organisme relais pour les prêts ; organisme de cautionnement bancaire ; commerçant de matériels ; commerçant de produits de la mer. C'est beaucoup pour une structure unique ! Aussi, dès qu'une des fonctions est mal assumée, les autres tendent à servir d'instrument de contrainte : un remboursement en retard (fonction 2) entraîne la saisie du moteur (fonction 3) ou des retenues sur la vente du produit (fonction 4), ou le retrait de la caution (fonction 1). Imagine-t-on que mon garagiste refuse de réparer ma voiture sous prétexte que je dois de l'argent à la banque ou que mon banquier puisse directement saisir cette voiture sans passer par la justice ?

Fatalement, le mélange de fonctions contradictoires au sein de coopératives conduit à leur échec, par désaffection assez rapide de la part des coopérateurs. Pourtant, il existe des coopératives qui marchent : elles ont une seule fonction et bien une seule. Ainsi, dans la pêche artisanale française, en Bretagne : il existe des coopératives d'avitaillement, d'autres de transformation des produits, d'autres de commercialisation (les Organisations de Producteurs), et la banque est elle-même coopérative (le Crédit Maritime Mutuel). Chacune des ces organisations coopératives a une fonction bien définie et exclusive.

On remarquera que la plupart des coopératives en Afrique, sinon toutes, sont des créations de l'extérieur du milieu. Souvent, leur création fut posée comme condition d'accès au crédit...

L'échec des coopératives n'a donc rien de bien mystérieux ni d'inéluctable ; il n'est pas imputable, comme on le lit trop souvent, à "l'individualisme" des pêcheurs.

### *3.2. Le remplacement des pirogues.*

Dès avant les indépendances, les projets de remplacement des pirogues par d'autres embarcations n'ont jamais cessé de se succéder les unes les autres, aussi bien en Mauritanie qu'au Sénégal ou en Côte d'Ivoire et au Bénin. Avec l' insuccès que l'on sait. Les arguments avancés en faveur d'un remplacement des pirogues vont du simplisme à des faits précis mais qui relèvent d'interprétations très différentes entre l'expert et les pêcheurs. Nous l'illustrerons dans le cas du Sénégal

- argument 1 : la pirogue est "traditionnelle", il faut la remplacer par une embarcation "moderne". Ce genre d'argument a, hélas, encore cours... En fait, la pirogue "traditionnelle" n'a cessé d'évoluer depuis le début du siècle comme l'a montré

J.P. Chauveau (1986). Pour finir, les pirogues de remplacement n'ont le plus souvent de "moderne" que le matériau, puisqu'elles reprennent des moulages de pirogues existantes. Entre "traditionnel" et "moderne", c'est en fait la rentabilité et la tenue en mer qui font la différence, jusqu'ici en faveur du "traditionnel".

- argument 2 : l'instabilité des pirogues. Cet argument est fondé, mais reçoit des pêcheurs une justification précise. L'instabilité, délibérément préservée, et compensée par du lest lorsque la pirogue est à vide, permet de faire l'économie de moyens de levage pour les grandes pirogues : il suffit que l'équipage se porte du même côté pour que le plat-bord vienne au niveau de l'eau, facilitant ainsi le chargement de la capture.

- argument 3 : les pirogues ont une faible rigidité. Argument fondé, mais là encore invoqué par les pêcheurs en leur faveur : la souplesse de la pirogue la rendrait plus confortable qu'une embarcation rigide sur une mer à clapot comme celle du Sénégal.

- argument 4 : les pirogues ont une faible étanchéité. Cet argument est admis par les pêcheurs, qui disent que l'amélioration de l'étanchéité doit être possible avec les pirogues actuelles.

- argument 5 : une supposée courte durée de vie. Les pirogues sont refaites à peu près tous les 7 ans et leurs éléments sont repris le plus souvent pour la construction d'une pirogue de taille inférieure à celle d'origine. Le madrier ou tronc de base est utilisé pendant plus de vingt ans. En termes de coût, le remplacement s'avère difficilement concurrentiel.

Les faits sont là, les remplacements n'ont pas eu de succès, et la pirogue continue son évolution endogène, en s'adaptant à la motorisation, puis à de nouveaux engins, à la conservation à bord...

### *3.3. Le projet CAPAS (Centre d'Assistance à la Pêche Artisanale Sénégalaise)*

Dans ce projet, il s'agissait initialement d'aider les coopératives *de pêcheurs* à s'assurer la maîtrise *de la commercialisation* de leur production, au motif qu'ils auraient subi une exploitation par les mareyeurs. Le projet visait donc sinon l'élimination, du moins une diminution du rôle des mareyeurs.

Les mareyeurs sont des commerçants et comme tels doivent avoir une activité rentable. Ce ne sont pas des philanthropes. Mais cela implique, dans le contexte sénégalais, qu'ils entretiennent avec les pêcheurs des relations non exclusivement marchandes, comme l'ont montré C. Chaboud et M.Kebe (1983). Les pêcheurs font l'avance du poisson ; en revanche, le mareyeur "fait les courses" du pêcheur en ville, lui fournit des avances de campagne, ou pour des fêtes familiales ou religieuses etc. Le rapport marchand est inséré dans des relations interpersonnelles complexes.

Le projet CAPAS reposait sur "l'encadrement" des coopératives et la formation des coopérateurs à la gestion des centres de mareyages comprenant véhicules, chambres froides et machines à glace. Le CAPAS n'a jamais commercialisé plus de 5 % des débarquements des lieux où étaient implantés les centres de mareyage. Au bout de six années, le projet a "baissé les bras" et les mareyeurs ont en partie pris le contrôle des centres de mareyage...

Il ne s'agit pas ici de faire l'analyse fine du projet CAPAS, ni de le considérer comme un échec total : il a eu des effets positifs directement et indirectement. Il s'agit par contre d'en examiner la genèse institutionnelle. A l'origine du projet se trouve une demande du gouvernement sénégalais au Canada. Puis des missions d'experts qui aboutissent à un projet lourd, techniquement et bureaucratiquement : importante infrastructure et importante administration. Le projet doit être expliqué aux pêcheurs auxquels il faut faire *"prendre conscience"* du besoin qu'ils sont censés avoir de ce projet. Il faut ensuite *encadrer* les coopératives. Enfin, la recherche n'est aucunement partie prenante à la genèse de ce projet.

Que ce projet soit canadien ne doit pas prêter à confusion : tous les pays et toutes les agences de développement ont connu des échecs répétés de leurs projets de développement.

### *3.4. Les projets "intermédiaires"*

Jusqu'à la Conférence Mondiale des Pêches à Rome, en 1984, la tendance la plus répandue en matière de développement des pêches considérait que l'évolution logique devait conduire les pêches piroguières de l'Afrique vers des formes

modernisées, voire industrielles. Dans le domaine des pêches comme dans d'autres, il s'agissait donc de mettre en place des "formes intermédiaires" de production (ou encore des "formes de transition") : il est attendu de ces formes de production qu'elles permettent l'apprentissage de l'industrie par les pêcheurs dits "traditionnels".

Au Sénégal, cette tendance a revêtu la forme des "cordiers", unités de douze mètres disposant d'une cale à glace et pouvant effectuer des marées d'une semaine. M.Kebe (1982) a publié une évaluation de la pêche cordière sénégalaise en plein déclin, et montré que :

- ces unités, qui nécessitent des structures portuaires, étaient utilisées et gérées comme des pirogues, avec entre autres, des arrêts durables du navire à l'occasion d'événements familiaux ou sociaux ;

- ces unités se retrouvaient en concurrence avec les pirogues sur les mêmes marchés, en situation défavorable.

Cette idée que l'évolution des formes de production soit liée à une question de difficulté technique est centrale dans ce que j'appellerai le "prêt à penser" du développement.

## 4. LE PARADIGME DES PROJETS DE DEVELOPPEMENT

### *4.1. L'économiste et le développeur*

En tant qu'économistes, nous avons développé des méthodes d'évaluation des projets qui, en principe valent pour tous les types de projets, une fois connus leurs objectifs et les moyens mis en oeuvre pour les atteindre. On peut avancer que les méthodes d'évaluation des projets sont "neutres" par rapport au type de projet analysé. Elles permettent de juger la cohérence interne et la faisabilité théorique du projet, mais ne disent rien sur sa pertinence (Squire et Van der Tak, 1975 ; Price Gittinger, 1985). Cette neutralité est à l'honneur de notre discipline ; mais à l'issue de plus de trois décennies d'échecs des projets, aussi bien évalués soient-ils (Banque Mondiale, 1986), nous sommes légitimement fondés à nous demander "si le roi est nu".

Tous les projets ont en commun :

- d'être issus d'un regard extérieur projeté sur une réalité sociale

- d'être initiés hors discussions préalable ni association avec les pêcheurs

- de pratiquer l'amalgame et le mélange des genres en préjugeant des objectifs qu'une communauté de producteurs assigne à son activité.

- d'être conçus sur un principe *d'encadrement* des populations visées.

Tout projet de développement initié de l'extérieur sur des objectifs et critères étrangers au groupe concerné se présente comme un ensemble d'a priori

- sur les intérêts individuels et collectifs

- sur les structures sociales ("réduire les inégalités")

- sur les comportements individuels et collectifs face au marché, au profit, au crédit.

### *4.2. Projet de développement ou projet d'accompagnement ?*

Tout projet de développement est basé sur une vision particulière de la réalité sociale dans laquelle il doit être implanté, que cette vision soit explicite ou, le plus souvent, implicite [1].

1. Il serait possible de classer les projets selon les théories de la croissance auxquels ils renvoient : théorie de la croissance harmonisée, "industries industrialisantes", "take off", import-substitution etc., mais ceci sort du cadre de cet exposé (cf. Weber 1978).

Les exemples présentés dans cet exposé amènent à considérer que les échecs répétés des projets de développement proviennent essentiellement de la notion même de *projet de développement.* Etranger à la société concernée, il conduit à *encadrer* les producteurs et, pour reprendre les termes en usage, à *les "conscientiser" :* il est fréquemment avancé qu'il faudrait *"changer les mentalités"* etc. Bref, faute d'avoir un projet appropriable par les producteurs, ce sera le projet qui tendra à s'approprier les producteurs...

Les *"success stories"* évoquées précédemment montrent que l'action des chercheurs, des administrations, des bailleurs de fonds, est *très* efficace lorsqu'elle *accompagne* des dynamiques *endogènes* de développement, leur donnant ainsi plein effet. Il est remarquable que cet accompagnement a lieu le plus souvent sans que l'administration ou les bailleurs de fonds n'en prennent réellement conscience. Il convient donc de les "conscientiser", et d'espérer que la notion de projet d'accompagnement se substitue un jour à celle de projet de développement.

Il ne s'agit pas d'un jeu de mots, mais bien d'une approche radicalement différente des problèmes de développement.

ABSTRACT

*The Canadian Atlantic Snow Crab Fishery as a system : variables, interactions and uncertainty.*

*The Canadian snow crab fishery began in 1966. Its evolution is the result of the conjunction of several factors. The systemic approach is used in this paper to analyze this fishery. The present work defines the major variables, the centres of decision and interactions. The four identified factors (resource, politics, economics and sociological factors) have different levels of importance in the evolution of any fishery but are particularily stressed out in this particular case. The social factor was at the origin of the fishery. The resource was not known precisely, but neither was it a constraint nor a factor of uncertainty, due to the accumulated virgin biomass. The explosive development (5000 mt captured in 1968, 48000 mt in 1982), was encouraged by a favourable economic situation (0.6 $ CAD/kg in 1980, 3.4 $ CAD/kg in 1988) and the political decision to give more licences to solve local social problems. In a following phase (1982-1988), the major source of uncertainty became the resource. Catches were decreasing almost everywhere with an unpredictable behaviour. Sociological problems appeared locally, especially in the processing sector, while the market stayed strong enough to maintain a reasonable income for the fishermen. In the later phase, both resource and economic factors became the main sources of uncertainty and risk (decreasing price and high variability in catch for certain areas). The market is essentially oriented towards USA and Japan and appear to be very sensitive to fluctuations in supply within these countries. The risks are presently supported by fishermen and the processing sector, acting in close interaction. Political factors played a dual role during those phases. Consider the development phase : on one hand it was spreading the risks and reducing uncertainty, through grants and support, but on the other hand it was increasing uncertainty through constant modification of the fishing regulations. Presently, political factor is a major factor of risk to the*

*fishermen, because the declared politics are to reduce the number of fishermen and processing plants. The sociological and economical factors may take on a greater importance in the near future because of this fact and because of the low possibilities of alternative employment for fishermen and plant workers.*

## 1. INTRODUCTION

Classiquement, on décrit le développement d'une pêcherie en trois périodes : (a) en développement ; (b) développée ; (c) en décroissance (souvent) ; (d) en effondrement, parfois (Garcia, 1984). Bakun *et al.* (1982) ont proposé une description de l'évolution d'une pêcherie et en parallèle la progression des connaissances scientifiques requises pour le suivi de cette pêcherie. Au début de l'exploitation (phase 1), la connaissance de l'extension et du potentiel de la ressource est nécessaire ; lors de l'expansion (phase 2), on cherche à définir les caractéristiques biologiques et écologiques de la population ; dans une phase de pleine exploitation (phases 3 et 4), on s'intéresse aux facteurs de croissance et de mortalité, à la prédiction des captures et aux estimations précoces de la force des classes d'âge. Un tel schéma ne tient compte, toutefois, que des connaissances strictement biologiques de la pêcherie. On sait que la ressource n'est pas seule en cause. Pour qu'une exploitation débute, une série de facteurs préalables doivent exister, parmi lesquels les conditions économiques (prix, marché) jouent un rôle important (Garcia, 1984). Il faut aussi que les technologies de capture et de transformation existent et à un coût « acceptable ». Enfin, il faut que des pêcheurs soient prêts à assumer le risque du développement. La ressource est ainsi une « variable » parmi les autres à l'intérieur du système (Brêthes et Fontana, 1992). Pour leur part, Chaboud et Fontana (1992) considèrent que la ressource fait partie d'un déterminant plus vaste du système (« le potentiel de production »), puisque si elle est « une condition nécessaire à l'activité de pêche, elle n'en est pas pour autant une condition suffisante ». Ressource et marché exercent des contraintes évidentes et représentent des incertitudes, à divers degrés, sur le développement et le maintien de la pêcherie. Le processus de gestion de l'exploitation, lui-même, devient une autre source d'incertitude (Hannesson, 1984), bien qu'il soit à la fois imposé à l'industrie et réclamé par elle (Anderson, 1984).

L'étude de la plupart des pêcheries mondiales a débuté alors que l'exploitation était déjà ancienne. La réglementation et les connaissances scientifiques se sont, dans la plupart des cas, mises en place bien après la phase de développement, parfois pour faire face à un effondrement, potentiel ou observé. La pêcherie du crabe des neiges de l'Atlantique canadien est récente. Elle s'est développée au début des années 1960 sur une ressource vierge dans un contexte global où existaient depuis longtemps une structure de recherche et un cadre juridique de gestion (« Fisheries Act », de 1867, amendé en 1961, et le « Territorial Sea and Fishing Zones Act », de 1964). Elle a connu une expansion particulièrement rapide (captures totales : 7 000 t, 1975, 15 000 t, 1980, 48 000 t, 1982) et concerne maintenant de nombreuses régions du golfe du Saint-Laurent (Fig. 1) et également, à un degré moindre, de la côte de Terre-Neuve. Son évolution récente (baisse des captures totales : 26 000 t en 1990, dont 10 000 t pour le Sud-Ouest) ; oscillation des prix) indique qu'elle est soumise à divers facteurs, internes et externes, dont l'importance s'est modifiée au cours de son évolution.

Le présent travail tente d'analyser le développement de la pêcherie de crabe des neiges du golfe du Saint-Laurent (côte est du Canada) sous un angle systémique. A partir de la structure de cette pêcherie, on va chercher à définir les variables du système, leur interaction et le rôle qu'elles ont pu jouer dans ce développement.

## 2. DONNÉES GÉNÉRALES

Le crabe des neiges, espèce d'eau froide et profonde, est pêché sur les vasières du golfe du Saint-Laurent, à des profondeurs généralement supérieures à 60 m (Fig. 1). Seuls les mâles de largeur de carapace égale ou supérieure à 95 mm sont exploités. Cette réglementation a été établie pour répondre d'abord aux exigences de l'industrie. Selon les hypothèses alors en vigueur, le potentiel reproducteur du stock devait être préservé : les femelles atteignent exceptionnellement la taille commerciale et les mâles deviennent physiologiquement matures vers 50-75 mm de largeur de carapace soit au moins un an avant d'entrer dans la pêche (Elner, 1982). Les crabes à carapace molle, venant de muer (« crabes blancs ») sont également exclus des débarquements en raison de la mauvaise qualité et du faible rendement en chair qu'ils procurent.

Le secteur de la transformation produit essentiellement de la section congelée (78 % des produits au Québec en 1990) et de la chair congelée (21 %). La vente de crabe entier est devenue une activité marginale mais elle représentait encore 9 % des ventes québécoises en 1989 (Boucher *et al.*, 1991). Le type de produit transformé répond à la demande des marchés d'exportation, où s'écoulent entre 90 et 95 % de la production. Selon les statistiques du Ministère des Pêches et des Océans, les deux principaux marchés sont les USA (30 à 45 %) et le Japon (30 à 60 %, en augmentation). La Communauté européenne (surtout Royaume-Uni, Belgique et France) est la troisième région d'exportation. Le marché européen a connu une baisse importante en raison de la montée de la valeur du Dollar à la fin des années quatre-vingt et de la concurrence des produits de substitution en provenance de l'Asie du Sud-Est.

L'intervention du Gouvernement est apparue assez tôt dans cette pêcherie, les permis spécifiques ayant été instaurés en 1972. Le cadre réglementaire a connu par la suite de nombreux ajustements pour répondre à la fois à l'expansion de la pêcherie, à la progression des connaissances, aux demandes de l'industrie et à des questions sociales. La gestion des pêches s'insère dans les principes généraux du Gouvernement du Canada :

(i) maintien de la ressource à un niveau optimal tout en protégeant le stock reproducteur ;

(ii) industrie de la pêche économiquement viable ;

(iii) maximisation de l'emploi.

D'une façon très générale, et pour l'ensemble des pêcheries canadiennes, on s'oriente vers une stratégie d'« effort constant » en se fondant sur le principe du « $F_{0.1}$ ». La réglementation agit soit sur les intrants (accès limité, limitation de la taille des navires, du nombre et du type d'engins, saison de pêche) soit sur les extrants (tailles minimales légales, quotas de capture). Dans le cas particulier du crabe, les données actuelles ne permettent pas d'utiliser les modèles classiques d'évaluation de stock, comme l'analyse séquentielle de population employée pour les poissons (Bailey et Elner, 1989), et on vise plutôt à ce que le taux de d'exploitation (capture/biomasse exploitable) soit compris entre 50 et 60 %. La biomasse est calculée soit à partir des statistiques de pêche (méthode « de Leslie ») soit par mesure directe (prospections par chalutage, marquages, etc.). La répartition des ressources halieutiques entre les différents acteurs cherche, par ailleurs, à optimiser les avantages socio-économiques. La pêcherie de crabe est ainsi divisée administrativement entre pêche semi-hauturière et pêche côtière. Cette répartition doit répondre aux critères suivants : proximité des côtes ; dépendance des communautés par rapport à ces ressources ; la spécialisation ou diversification potentielle des flottilles. Les 130 crabiers semi-hauturiers appartiennent essentiellement au Nouveau-Brunswick et au Québec et ils exploitent le stock du sud-ouest du Golfe, entre la baie des Chaleurs et les îles de la Madeleine (Fig. 1). Cette pêcherie correspond à l'exploitation « historique », dans la mesure où ce sont ces pêcheurs qui ont été les premiers à obtenir des permis de pêche au crabe. Pêche semi-hauturière et pêche côtière se différencient par le nombre de casiers autorisés (150 dans le premier cas, de 50 à 75 dans le deuxième, sauf droits historiques) et la taille des bateaux utilisés.

Dans l'optique du maintien de la ressource à un niveau optimal, la réglementation actuelle de la pêche au crabe a adopté un éventail de moyens portant à la fois sur des aspects biologiques (protection des femelles et des crabes blancs, taille minimale de capture, dès 1976) ; sur la capacité de capture (nombre de casiers/permis) ; sur la saison de pêche (durée fixe, 10 semaines pour les semi-hauturiers en 1986 ; ou variable selon les quotas ou l'apparition du crabe blanc) ; et sur le cadre législatif : accès limité (1975), zones de pêche côtière (Moyenne Côte-Nord : 1978 ; Basse Côte-Nord : 1980 ; île du Prince-Édouard : 1984), quotas (semi-hauturiers : quota global en 1986, quota individuels en 1991 ; côtiers : quota individuels, en 1983 pour la Basse Côte-Nord, 1991 pour la Moyenne Côte-Nord et 1992 pour la Haute Côte-Nord).

L'accroissement de l'exploitation correspond principalement à l'octroi de nouveaux permis pour la pêche côtière (Fig. 2), qui a débuté en 1978 au Cap-Breton et dont le nombre atteint actuellement 250 répartis sur neuf zones dans le Golfe. A cette augmentation du nombre de permis s'est ajoutée une expansion de l'aire exploitée (dans tous les secteurs) et une progression du nombre autorisé de casiers pour la pêche côtière, passant de 25 ou 30/permis en phase dite « exploratoire », à 50 par la suite. Durant cette période, on a également assisté à une modernisation des techniques : accroissement de la taille des navires, généralisation du radar, des systèmes de positionnement électroniques et de l'éclairage pour travailler de nuit, modification des casiers (Chiasson *et al.*, 1992). La capacité globale de capture est stabilisée depuis 1986. La diversification des flottilles est nette puisque la plupart des pêcheurs ont conservé les autres permis qu'ils détenaient et plus de la moitié en possèdent trois, surtout pour le poisson de fond (Fig. 2). L'usage effectif de ces autres permis est variable. Peu fréquent dans la pêche semi-hauturière, il est général pour la pêche côtière, pour laquelle la capture du crabe est considérée comme une activité économique complémentaire (Bailey et Elner, 1989). La diminution des captures a toutefois augmenté l'utilisation des permis additionnels : au Nouveau-Brunswick, le

pourcentage de pêcheurs qui ont utilisé une combinaison de permis est passé de moins de 20 % en 1974-1976 à plus de 40 % en 1989 (Chiasson *et al.*, 1992). Le secteur de la récolte emploie environ 1 300 personnes pour l'ensemble du Golfe (550 pour la pêche semi-hauturière).

## 3. LE SYSTÈME DE LA PÊCHE : RÔLE DES ACTEURS

Les données générales de la pêche permettent de réaliser un schéma conceptuel du système qu'elle constitue (Fig. 3), faisant ressortir les diverses variables impliquées : sociale (comportement des pêcheurs, effets en retour), économique (influence des marchés internationaux sur les prix et la rentabilité des flottilles), politique (stratégie générale de l'État, réglementation) et biologique (situation et évolution de la ressource). En reprenant, par ailleurs, les phases de développement définies par Bakun *et al.* (1982), on peut retracer les grandes étapes de l'évolution de cette pêcherie de crabe des neiges et le rôle respectif que ces variables ont pu y jouer. On regardera principalement le cas de la pêche semi-hauturière, la plus ancienne et la plus importante. Le cas des pêcheries côtières ne sera considéré qu'à travers les questions spécifiques qu'elles posent.

La ressource constitue classiquement un pivot du système. On constate toutefois que son « rôle » principal, en début de développement a été seulement d'exister. En effet, l'exploitation a débuté sur la constatation de sa présence avec un potentiel qui paraissait suffisant aux pêcheurs. Les quelques données biologiques préalables semblaient indiquer une abondance limitée et ne laissaient pas prévoir de grandes possibilités économiques (Brunel, 1962). L'initiative est donc venue du milieu de la pêche, qui a poussé les biologistes du Gouvernement a réaliser des prospections plus exhaustives. Le stock du sud-ouest du Golfe a été jugé pleinement exploité successivement en 1971 (Watson et Wells, 1972) puis en 1977 (Lamoureux et Lafleur, 1982). L'effort de pêche exercé dans cette région a augmenté jusqu'en 1980 et les captures ont suivi cette augmentation (Fig. 4), ce qui semblait confirmer les intuitions de la profession. Lors de cette « phase 1 » (début), on doit admettre que c'est la dynamique sociale qui a joué le rôle principal, par l'action de pêcheurs opportunistes (les pêcheurs « stochastiques », au sens de Allen et Mcglade, 1986, à la recherche du meilleur rendement « possible »). La contrainte principale s'est révélée être, toujours dans cette phase, la variable économique. En effet, les premiers efforts, venant des pêcheurs de l'île du Prince-Édouard, se sont soldés par un échec en raison de l'absence de marché. Il a fallu la chute importante de la pêcherie de crabes d'Alaska, fondée sur l'exploitation de plusieurs espèces, pour accroître la demande et permettre au crabe des neiges canadien de s'implanter.

L'expansion (« phase 2 ») n'a donc pu avoir lieu que dans la mesure où l'exploitation s'est avérée rentable financièrement, avec une bonne rémunération du risque (rapport interne de Pêches et océans, 1985). Les captures provenant du stock du Sud-Ouest ont alors crû régulièrement jusqu'en 1982, passant de 4 000 - 7 000 t durant la période 1968-1975 à 26 000 t en 1982. Face à ce développement explosif, le rôle du pouvoir politique est devenu particulièrement important, avec la mise en place progressive de politiques de gestion de plus en plus contraignantes (instauration d'un système de permis, accès limité, fixation des niveaux d'effort, instauration de saisons de pêche et enfin de quotas). Cette phase a été relativement brève. Il y a eu un apprentissage rapide des techniques de capture et du comportement de l'espèce du côté des pêcheurs. Ainsi, l'effort de pêche du Sud-Ouest s'étant théoriquement stabilisé (dans la mesure où les règlements ont pu ne pas être strictement respectés) dès 1980, l'augmentation des débarquements est sans doute reliée à l'extension des zones prospectées, à une meilleure performance des unités de capture, en raison des améliorations technologiques (Chiasson *et al.*, 1992) et, peut-être, à une augmentation du recrutement au sein de la ressource. Le développement général de la pêcherie correspond ensuite à la mise en place des zones de pêche côtière.

Le démarrage de la pêche côtière a été différente de celle du Sud-Ouest. Exception faite de la zone de l'île du Prince-Édouard, qui a été instaurée à la suite de pressions locales, ces pêcheries ont été créées à l'initiative du Gouvernement du Canada dans le but de favoriser l'émergence d'industries régionales avec accès exclusif pour un petit nombre de pêcheurs (Bailey et Elner, 1989). La variable politique a donc été déterminante dans ce développement. Les permis ont alors été octroyés sur une base volontaire, dans un premier temps à titre expérimental, puis de façon permanente. L'évolution de la pêcherie a varié selon les zones : captures relativement stables sur les Moyenne et Haute Côte-Nord (autour de 2 000 t et 1 000 t, respectivement) ; décroissance rapide et brutale sur la Basse Côte-Nord où les débarquements sont passés de 2 200 t en 1986 à 168 t en 1989, avec une légère reprise à 740 t en 1991.

La phase de pleine exploitation (« phase 3 ») a fait apparaître deux niveaux d'incertitude. Le problème est d'abord venu de la ressource. Les captures ont commencé à décroître dès 1983 (Fig. 4) et, en 1990 dans le Sud-Ouest, elles n'étaient

plus que de l'ordre de 50 % de celles de 1982. Cette incertitude s'est accrue par la suite avec l'acquisition de nouvelles données biologiques. Alors que l'on pensait que les mâles connaissaient une croissance continue, il apparaît que cette croissance peut être interrompue avant l'atteinte de la taille légale (« mue terminale »). Seuls les individus ayant atteint ce stade seraient capables de s'accoupler efficacement (Conan et Comeau, 1986). Ainsi, la taille légale actuelle ne garantirait plus la protection du potentiel reproducteur du stock, ce qui pourrait hypothéquer le maintien à long terme de la population. De plus, un contexte de rationalisation de la flotte a fait en sorte que les mesures de protection se sont accrues avec la mise en place de quotas par entreprise. Les aspects économiques, ensuite, ont révélé la grande dépendance de la pêcherie vis à vis des marchés extérieurs. L'expansion s'était déroulée dans un contexte favorable de diminution des captures japonaises et américaines et d'un accroissement de la demande sur le marché japonais (Fig. 4). L'offre canadienne s'est avérée essentiellement « preneuse de prix », n'ayant aucune influence sur leur formation (Michaud et Abgrall, 1985). Ces prix apparaissent fortement reliés, par exemple, à la situation des inventaires des industries américaines (Fig. 4). Cette situation devient particulièrement cruciale dans la mesure où les captures de *Chionoecetes* ont augmenté de façon dramatique depuis 1985 dans le Pacifique Nord-Est (Fig. 4). Cette dernière période a également vu le développement de productions concurrentes d'Asie et d'Amérique latine (selon la FAO, les captures mondiales, toutes espèces confondues, sont passées de l'ordre de 800 000 tonnes en 1982 à 1 100 000 tonnes en 1989) et du simili-crabe (« surimi »), dont la consommation américaine a progressé de 20 000 t en 1984 à 68 000 t en 1989 (source : Pêches et océans). De fait les prix au débarquement dans l'Est canadien sont à la baisse depuis 1989, étant passé de 4 $[1]/kg en 1988 à 2,6 $/kg en 1991. Cette tendance semble se poursuivre en 1992. Associée à la chute des captures, la baisse des prix a fait passer la valeur des débarquements de 98 millions de dollars en 1988 à 49 millions en 1990.

## 4. PÊCHERIE ET ÉCONOMIE LOCALE

Les tendances observées ont des effets en retour sur la dynamique sociale et économique et affectent en premier lieu les revenus des pêcheurs. Une étude complète a été réalisée pour le Québec (Boucher *et al.*, 1991). En considérant le revenu de trésorerie [2], on constate, pour la pêche semi-hauturière, que ce revenu moyen est passé de 51 000 $ en 1984 à 207 000 $ en 1988. La progression des prix sur le marché international a ainsi réussi à compenser l'effondrement des débarquements, ce qui n'a plus été le cas par la suite : le revenu moyen a chuté à 21 000 $ en 1990, en raison de la baisse conjointe des prix et des captures. En 1991, une légère reprise est observée (51 000 $). Les revenus de la pêche côtière sont plus faibles et varient d'une région à l'autre, avec des tendances sensiblement identiques à celles de la pêche semi-hauturière.

La pêche a un impact important sur les communautés maritimes de l'est du Canada, où plus de 30 % des emplois dépendent de cette activité (46 % aux îles de la Madeleine ; 80 % sur la Basse Côte-Nord). La plupart des communautés de pêche est implantée dans des villages et la majorité des emplois offerts par la pêche se trouvent dans ces villages côtiers (Kirby, 1982). Par ailleurs, il est fréquent que plus d'une personne par ménage aillent à la pêche, tandis que les employés d'usine sont constitués à plus de 10 % par des personnes appartenant à des ménages de pêcheurs. On conçoit donc que le crabe des neiges, en progression tant en quantité qu'en valeur, ait été perçu comme pouvant jouer un rôle moteur dans les économies locales. C'est d'ailleurs ce qui motivé la création des pêcheries côtières. De fait, l'incidence sur le niveau de l'emploi a été notable. En 1988, 21 % des emplois directs issus de la pêche québécoise étaient reliés au crabe. Les activités de transformation ont subi de plein fouet la baisse de la production. De 1986 à 1989 au Québec, le nombre d'emplois dans les usines traitant le crabe a diminué de 50 %, passant de 2000 à 1000. Il a légèrement réaugmenté en 1990 et 1991 (1300) en raison de la reprise des débarquements et de la production de chair (Boucher *et al.*, 1991).

L'action des pouvoirs politiques, ne concernant pas seulement la réglementation, a également favorisé l'expansion et le maintien de l'activité halieutique. La pêche a bénéficié d'aides financières de divers ordres. Les programmes ont été orientés essentiellement vers la modernisation des entreprises. On espérait ainsi concurrencer les autres États pêcheurs. Dans le secteur de la collecte, l'aide s'est manifestée sous la forme du Programme d'aide aux bateaux de pêche, instauré

1. L'unité monétaire est le Dollar Canadien (1 $ CAD ≈ 0,8 $ US).
2. Le revenu de trésorerie correspond au revenu brut diminué des dépenses (salaire de l'équipage et intérêt) et du remboursement en capital : il correspond donc au salaire du capitaine plus la rémunération pour le risque (avant impôt). Il ne tient donc pas compte de dépenses «comptables» qui n'entraînent aucun déboursé d'argent (amortissement et rémunération en capital).

pour fournir aux exploitants des capitaux quand il n'y avait que peu de ressources disponibles (Crowley *et al.*, 1990). L'aide globale, incluant des subventions directes et des garanties de prêts à taux préférentiel, pouvait atteindre 85 % des frais occasionnés par l'achat de bateaux neufs semi-hauturiers, incluant les aides des gouvernements provinciaux. Pour la pêche côtière, l'investissement personnel était plus élevé (25 % ; source : Pêches et océans). En 1984, les aides gouvernementales ont permis d'accroître les revenus nets des bateaux de 12 % au Québec (source : Pêches et océans). Les programmes d'aide directe ont été arrêtés en 1986, d'une part en raison de la surcapacité de capture des flottilles canadiennes et d'un changement de philosophie, les principes de l'économie libérale prenant le pas sur les principes d'assistance. On constate, selon les informations de Chiasson *et al.* (1992), que la modernisation de la flotte a été pratiquement arrêtée à cette date.

Une aide importante provient de l'assurance chômage. Ce programme assure un revenu additionnel aux pêcheurs (propriétaires ou marins) entre deux saisons. La durée des prestations vont de 15 à 25 semaines (Crowley *et al.*, 1990). Leur importance dans le revenu total des pêcheurs est variable selon les années mais elles peuvent en représenter 10 % pour un capitaine et 16 % pour les marins, ce qui en fait un apport non négligeable. Depuis 1990, l'assurance chômage doit s'auto-financer. Considérant que les primes versées sont supérieures au montant des cotisations perçues, une partie de cette aide est maintenant prise en charge par l'ensemble des travailleurs canadiens.

## 5. DISCUSSION

La pêcherie de crabe des neiges du golfe du Saint-Laurent a connu toutes les phases d'un développement classique mais dans un laps de temps très court. A un début rapide et une expansion quasi explosive a fait suite, non moins rapidement une phase de décroissance à la fois dans les captures et dans les prix. Lors de chaque phase du développement, il a existé des niveaux de risques liés aux incertitudes sur plusieurs variables externes au secteur de la récolte : ressource, réglementation et marché.

Les incertitudes sur la ressource été accentuées par le fait que la pêcherie a exploité la biomasse vierge d'une espèce peu et mal connue. Elles correspondent aux interrogations que se posent les biologistes sur son taux réel de production, sur l'incidence de la pêche sur son maintien à long terme et sur l'effet éventuel de l'environnement écologique sur le recrutement à la pêche. On peut supposer que l'avancement des recherches en cours permettra de diminuer le niveau d'imprécision pour cette variable.

Les instances gouvernementales ont eu un rôle contradictoire. D'une part, elles ont octroyé des aides pour augmenter la performance des flottilles (particulièrement au Québec, qui visait à rattraper le retard sur les autres Provinces de l'Est canadien) ; ces aides, organisées selon des plans à moyen terme pour l'ensemble des pêcheries, se sont poursuivies alors même que la ressource était en déclin. D'autre part, comme le souligne Hannesson (1984), le processus de gestion est devenu, assez vite, une nouvelle source d'incertitude. D'une attitude plutôt neutre, ou sceptique, au début de l'exploitation, le Gestionnaire a progressivement assuré un contrôle de plus en plus étroit sur la pêcherie. Selon les processus de décision actuels du Ministère des pêches et des océans, le plan de gestion des espèces exploitées commercialement est établi pour une année. Ce système ne pose pas de problème important dans un contexte stable. Dans le cas du crabe, les modifications ont été fréquentes, particulièrement en fin de la phase d'expansion et dans la phase de plein développement où l'état de la ressource est devenue préoccupante. Ainsi, pour la pêche semi-hauturière, en 1984, le quota de 24 000 t a été haussé à 26 000 t en cours de saison, puis organisé sous la forme de quotas hebdomadaires par bateau (pour étendre la saison de débarquement sous la pression des travailleurs d'usines) ; en 1985, le quota était de 26 000 t et il y a eu extension de la saison après atteinte de ce quota ; la diminution des quotas a été régulière chaque année jusqu'en 1990. En 1991, un effort est réalisé en établissant un plan de deux ans avec un quota annuel de 10 000 t réparti individuellement (80 % partage égal, 20 % calculés sur les prises historiques), mais révisable en fonction des évaluations faites de la ressource (il a été ainsi augmenté à 12 000 t en 1992). Dans un tel contexte en perpétuelle évolution, l'établissement de plan d'investissement, la négociation avec les acheteurs, etc., deviennent particulièrement problématiques. Les tendances récentes de la gestion, toutefois, cherchent à amoindrir ces incertitudes en associant la profession au processus de décision. Ainsi en 1990, les pêcheurs semi-hauturiers ont accepté de ne pas augmenter les quotas pour laisser dans la mer un peu du « capital biologique » de l'année, en espérant ainsi faciliter la récupération du stock.

Les aspects économiques sont de plus en plus importants à l'heure actuelle. La pêche a pu se développer dans un contexte international favorable. Mais la pêcherie est liée à une évolution des prix est sous le contrôle des grossistes étrangers (américains et japonais).

Dans ce contexte « incertain », le développement de l'exploitation a représenté des risques. Ce risque est assumé à plusieurs niveaux, mais sous des formes différentes et variables selon le stade de développement de la pêcherie (tableau 1). Pour le pêcheur, toute sortie en mer est un « pari » dans un jeu de hasard (Gates, 1984). Les individus qui se sont engagés dans ce nouveau type d'exploitation ont dû assumer un risque élevé, n'ayant aucune certitude d'obtenir de bénéfice sur leur investissement, financier et humain. L'incertitude sur la ressource et sur les marchés est sans doute la plus élevée au début de l'exploitation. Pour la communauté, les impacts potentiels sont encore faibles, la nouvelle activité ne modifiant pas profondément les habitudes et pratiques locales. L'industrie est liée à la fois à la garantie d'approvisionnement (la ressource) et à la garantie de vente (le marché). Le risque est alors élevé, puisqu'elle doit investir dans des technologies adaptées. Pour les instances de gestion, les problèmes sont d'une autre nature, surtout dans la mesure où il n'existe aucune donnée préalable. Freiner l'activité à son début peut nuire au développement, par contre, refuser tout contrôle peut amener à la destruction d'une ressource. Aussi, un moyen terme est-il adopté, avec un minimum de règlements. A cette étape, la réglementation n'a donc pas représenté d'incertitude. Le Gouvernement prend, par contre, des risques plus concrets en s'impliquant directement, et financièrement, dans la pêche au crabe des neiges, par le biais des aides à l'investissement, mais aussi en encourageant, ou favorisant, l'ouverture de nouvelles pêcheries côtières dont on ne pouvait prévoir le devenir. A ce début d'exploitation, on doit admettre qu'il y a un certain partage des risques entre les intervenants, même s'il existe une disymétrie du côté des industries de capture et de transformation.

En phase d'expansion, les niveaux d'incertitude changent. Les captures suivant l'augmentation de l'effort, les marchés répondant bien à l'augmentation de l'offre, ces éléments n'apparaissent plus comme facteurs de risque importants, bien que le spectre des fluctuations d'abondance et de prix soit toujours présent. Ce risque est, par contre, toujours bien rémunéré par les revenus que cette pêche génère. Pour le Gouvernement, la ressource commence à devenir un élément de crainte, puisque l'on ne sait pas quel niveau d'exploitation elle pourra supporter à long terme, et les contrôles deviennent de plus en plus serrés. L'accroissement, et la multiplication, des mesures restrictives de gestion deviennent, dans cette situation, de nouveaux facteurs d'incertitude pour le pêcheur. Le risque s'élève pour les communautés, puisque la nouvelle pêcherie génère des activités économiques spécifiques, donc éventuellement vulnérable. Par ailleurs, l'accès limité à une ressource profitable crée localement des clivages sociaux avec des modifications de la structure même de la communauté, comme cela a été observé sur la Basse Côte-Nord : aggravation des disparités sociales, diminution de l'esprit de solidarité (Breton, *in* Brêthes et Breton, 1992).

Dans la pêcherie développée, puis en décroissance, l'évolution des captures et des marchés met les activités de récolte et de transformation dans une situation périlleuse. Le risque s'accroît à tous les niveaux, la réglementation devenant extrêmement contraignante et ayant des répercussions en aval sur les usines de transformation. Pour limiter les problèmes socio-économique, le Gouvernement accepte de prendre un minimum de risques sur la ressource et, par conséquent, sur la réglementation, qui est un peu moins draconienne que ce qui est suggéré par les données biologiques. On note ici l'importance des délais de réaction du processus de gestion et de l'inertie propre au système, notamment le déphasage entre les aides (maintenues dans un contexte biologique douteux) et les contraintes à l'exploitation. Au niveau social, le contre-coup de la décroissance peut être sévère avec la diminution des activités rémunératrices. Les pertes d'emploi, l'endettement des ménages, contracté pendant la phase favorable, deviennent problématiques, surtout si le tissu social a pu se distendre à l'intérieur des collectivités.

Il est intéressant de constater qu'au cours du développement de cette pêcherie, les préoccupations gouvernementales ne se sont portées ni sur les marchés ni sur les aspects sociaux (mise à part l'assurance chômage) et que son action, notamment par l'octroi de subventions et de permis sur une base volontaire, a pu avoir un effet pernicieux et imprévu au niveau des communautés.

Dans le cas de la pêche au crabe, on constate que le niveau de partage des risques s'est modifié au cours du développement, avec le retrait progressif des pouvoirs politiques dans le soutien à l'industrie. Assumé au départ par les pêcheurs, la transformation et le Gouvernement, le risque apparaît maintenant devoir être pris en charge par l'ensemble du secteur social et économique. Dans une certaine mesure, les pêcheurs ont « prévu » les problèmes potentiels. Ils ont investi dans les moyens de capture (nouveaux bateaux, nouveaux équipements) afin de s'assurer une plus grande efficacité et ce d'autant plus que la pêcherie a longtemps été gérée sous un régime de quota global. Beaucoup ont également conservé leurs autres permis de pêche. La revitalisation de ces permis, particulièrement dans la pêche côtière, apparaît comme une solution aux problèmes du crabe. Ainsi, sur la Basse Côte-Nord, alors que les captures de crabe baissaient de 2000 à 160 t entre 1987 et 1989, les captures de morue passaient de 490 à 1500 t au cours de la même période pour les crabiers (Lalande et Dubé, 1990). Ce remède n'est toutefois que partiel dans un contexte de crise généralisée (les valeurs globales des débarquements des crabiers ont baissé de 5 millions $ entre 1987 et 1989 sur la Basse Côte-Nord).

Dans l'environnement politique actuel, tant national qu'international, il semble douteux que le Gouvernement en revienne à un véritable partage des risques. L'industrie doit trouver elle-même les moyens de résoudre ses problèmes. Dans la mesure où l'on ne prévoit pas de véritable reprise à long terme de la ressource aux niveaux connus antérieuremment et où la gestion paraît de plus en plus efficace pour éviter une récolte abusive et amortir les grandes fluctuations des débarquements, les incertitudes principales paraissent être d'ordre social et économique. On cherche déjà à sortir de la dépendance des grossistes étrangers en misant sur la qualité de produits négociés directement avec des acheteurs. On étudie des possibilités de stabulation pour approvisionner les marchés intérieurs en dehors de la saison officielle. D'autres approches innovatrices sont à rechercher. Quel en sera le coût pour les collectivités, dans un contexte de « rationalisation » ? Cela reste à déterminer.

# Development and Diversification : Sustainability Strategies for a Costa Rican Fishing Cooperative

**Anthony T. Charles[a] and Angel Herrera[b] ***

[a]Department of Finance and Management Science, Saint Mary's University, Halifax, Nova Scotia B3H3C3 CANADA

[b]School of Biological Sciences, Universidad Nacional, Heredia, COSTA RICA

ABSTRACT

*"Successful" fishery development can be defined as the simultaneous achievement of ecological, socioeconomic, community and institutional sustainability. This paper incorporates these sustainability elements within an integrated framework, which is applied in a case study of Puerto Thiel, a fishing community in the Gulf of Nicoya on Costa Rica's Pacific coast. The economic performance of the local fishing cooperative is analysed, and experiences with economic diversification are reviewed. We highlight the importance, especially in heavily exploited fisheries, of policies that simultaneously pursue development (to increase local socioeconomic and community fishery benefits within resource limitations) and economic diversification (to lessen the impact of fishery management restrictions by creating non-fishery employment alternatives).*

## 1. INTRODUCTION

Why have fishery development efforts experienced at best a mixed record of success ? Contrary to the perceptions of some development agencies, failures in fishery development can be traced not to the intractability of fishery problems themselves, but rather to overly-narrow approaches that have been used in tackling these problems. This paper attempts to formulate and to apply an integrated view of fishery development, situated within a modern context of sustainability.

* We are grateful to the Fishery Resources Management Section of the Universidad Nacional's School of Biological Sciences, and to the Economic Sciences Research Institute of the University of Costa Rica, for use of their facilities. Financial assistance from the Science Subvention Program of Canada's Department of Fisheries and Oceans, and from the Natural Sciences and Engineering Research Council of Canada, grant #A6745, is gratefully acknowledged.

In the following section, a conceptual framework of sustainable fishery development is developed. This is applied in sections 3, 4 and 5 to an examination of development, diversification and sustainability options for Puerto Thiel, in Costa Rica's Gulf of Nicoya. In section 3, the relevant fishery environment, fishing approaches, and recent economic history are described. Section 4 analyses the performance of the community's fishing cooperative, while in section 5, we examine experiences in non-fishery economic diversification. Finally, a number of conclusions are presented in section 6.

## 2. SUSTAINABLE FISHERY DEVELOPMENT

Thanks to the Brundtland Commission (WCED 1987), it has become increasingly clear that, whatever other objectives are pursued in the economy, the goal of "sustainable development" must be paramount. In the fishery context, this implies that policy proposals must be judged primarily on their contribution to fishery sustainability. But what exactly constitutes a "sustainable fishery" ? This section presents an integrated bio-socio-economic perspective, addressing in particular the key links between diversification and sustainability.

### *2.1 The Idea of Sustainability*

In broad terms, sustainable development involves the simultaneous pursuit of : (a) ecological, (b) socioeconomic, (c) community and (d) institutional sustainability. These criteria can be portrayed within a "Sustainability Triangle" framework (Charles 1994) :

> i) Ecological Sustainability...ensuring that the capacity and quality of the relevant ecosystem, and of each species therein, are maintained or enhanced over time.
>
> ii) Socioeconomic Sustainability... ensuring that (a) net benefits are as great as possible and as well distributed as possible amongst participants, and (b) viability is maintained within both the local and the global economy.
>
> iii) Community Sustainability... to maintain or enhance the social, cultural and economic welfare of communities -- both those dependent on the fishery and those affected indirectly by the fishery.
>
> iv) Institutional Sustainability...ensuring that institutional structures (including financing and administrative capabilities) are sufficient to maintain fishery management and development measures in the long term.

Fishery development policy can be viewed as sustainable ONLY IF it enhances, or at least maintains, each of the above components over time. This requires an integrated process of "sustainability assessment", in place of narrow uni-disciplinary measures of success such as economic efficiency.

### *2.2 Economic Diversification and Sustainability*

The fisheries of developing regions typically face a trio of key problems ; over-exploited stocks, an over-extended fleet, and a lack of alternative employment outside the fishery. In addressing these, the late economist Ian Smith (1981) expressed well a fundamental but oft-neglected reality : to be just, feasible and effective, policies cannot be restricted to resolving one or two of these problems alone. This key point, an insightful forerunner to multi-faceted concepts of "sustainable development", extends the conclusion of modern fishery economics that "bio-economic" management is needed to tackle even apparently biological problems. In other words, simple attempts to promote biological sustainability may reduce economic sustainability.

This realization, and the subsequent emphasis on "bio-economic" management, led to frequent promotion of policies to reduce the number of fishers through so-called "rationalization". However, one of Smith's key contributions was to point out that such a "release of labour" from the fishery may well be a social bad, except in rare cases where a high-employment economy is waiting to absorb labour for productive uses. He noted that in the absence of non-fishery economic alternatives, rationalization may (a) impose inhumane and hence nonsustainable impacts on those dependent

on the fishery, or (b) fail to be feasible politically, due to negative community-level effects or (c) fail from a practical perspective, since fishers without other options will do anything, legally or illegally, to maintain their livelihood. Hence, "bio-socio-economic" policies are required, to enhance ecological and economic sustainability while also incorporating community sustainability. These considerations will be examined further in the following case study.

## 3. THE GULF OF NICOYA AND PUERTO THIEL

The Gulf of Nicoya, on Costa Rica's Pacific coast, is the country's principal artisanal fishing area (Fig. 1). For physical, biological and management reasons, its area of 1500 $Km^2$ is divided into two parts, the "outer zone" and "inner zone" (Carranza 1985) ; it is the latter, dominated by coastal mangroves and small-scale fishing, that is the focus here. Shallow throughout and protected from the open sea, the inner Gulf provides a favorable environment for mangroves, which represent a crucial coastal habitat in many tropical regions. In the Gulf, mangroves cover 112 km (42.6 %) of the coastline and 15,174 ha of coastal area (Solórzano et al., 1991).

### *3.1 The Gulf of Nicoya Fishery*

Historically, the principal economic activity in the internal part of the Gulf was a traditional artisanal fishery, using longlines and gillnets to harvest a variety of fish stocks. This open access fishery experienced relatively low profitability, and required little in the way of government management efforts.

The situation changed dramatically in the early 1980s, with the introduction of a modified gillnet technology for catching white shrimp (genus *Penaeus*). These shrimp stocks rapidly became the most desired catches for fishers, although there remains commercial interest in a variety of finfishes, such as corvina (croaker), red snapper and snook, as well as the bivalve "pianguas" (genus *Anadara*), which grows on the roots of certain mangroves (genus *Rhizophora*).

Without changing the small-scale nature of the fishery, the shrimp harvest led to increased profitability, and (as would be expected in a relatively open access fishery) an increased migration of people from other areas to fish in the Gulf. In fact the number of *licensed* fishers grew from approximately 2000 in the early 1980s to reach almost 3000 today, while approximately 3000 more fish illegally without licenses. The capital stock of boats fishing in the Gulf has also increased dramatically (Figure 2). The number of small "botes" increased steadily since the mid 1970s, while the number of larger "pangas" grew rapidly between 1984 and 1988, reflecting a process of technological change in the fishery. In the late 1980s, this expansion began to slow, and was largely halted in 1989-90 by a ban on new boats in the area.

The rapid transformation in the fishery took place in the absence of adequate planning, so that by 1985 a substantial decline in the catches of shrimp was being felt. This led to what is still the major conservation management tool in the inner Gulf region, a 3-month closed season on shrimp harvesting between May and July each year. As well, other regulations have been implemented in the Gulf, including a limitation on gillnet mesh size (Herrera and Valerín, 1992).

### *3.2 Puerto Thiel*

Puerto Thiel is a small fishing community located on the northwest side of the Gulf. From the final years of the 19th century to the mid-1950s, it was a port for coastal trade, but has gradually transformed into a fishing community as water travel gave way to road transportation. Today the roughly 160 permanent residents depend largely on the fishery for their livelihood. Surrounded by coastal mangroves and two large cattle ranches, there are few nearby agricultural opportunities. However, despite a widespread lack of agricultural experience, current economic difficulties have led to seasonal migrations of Thiel residents to work in coffee and sugarcane harvesting in interior zones of the country.

### *3.3 The CoopeThiel Fishing Cooperative*

"CoopeThiel" was formed in 1984, began operating fully in 1986, and currently has a membership of 23. The cooperative's principal operation is a fish handling and storage centre, with offices, fish receiving space, cold storage and an ice machine. This facility provides important social benefits both to members and to other local fishers, being the community's sole year-round fish buying site.

CoopeThiel also maintains a fishing fleet of 10 wooden outboard-motor boats, averaging 6m in length. This fleet comprises a third of the community's vessels, but just one-sixth of those fishing from Thiel during the main shrimp harvesting months, when seasonal fishers and their roughly 30 vessels arrive from other locations. Shrimp gillnets are the principal fishing technology used by Thiel fishers, except in the closed season for shrimp, when rudimentary long-lines and large-mesh gillnets transform the fishery into a more selective activity targeting exclusively on fishes.

CoopeThiel's economic performance has been generally acceptable to its members. Although dividends have never been paid, it is recognized that members of the cooperative obtain sufficient to provide a minimal standard of living for their families. However, faced with increased concern over the state of Gulf of Nicoya fish stocks, future cooperative finances, and the general socioeconomic welfare of the membership, the cooperative has expressed an interest in (a) better understanding its recent economic record in the fishery, and (b) pursuing innovative ideas to diversify its economic activity. Results to date in each of these areas will be described in the following sections.

## 4. COOPETHIEL : AN ECONOMIC ANALYSIS

CoopeThiel maintains full records of its fish buying and selling activities, records which were made available for analysis to the Fishing Community Extension Program of Costa Rica's Universidad Nacional. The results reported here are based on almost 3000 landings receipts representing payments to fishers for harvests obtained through approximately 6000 days of fishing over the 3-year period from April 1988 to March 1991. Using this primary data, which also includes information on fishing costs (for gasoline, ice, cooperative service fees, etc.) it has been possible to obtain a rare detailed view of fisher activities in the Gulf.

It should be noted here that, unless stated otherwise, all catches, costs and incomes are on a "per day" basis, and all monetary figures are given in real terms, in January 1988 colones (US$1 = 85 colones approximately). Inflation of 200 % occurred over the period 1988-1991, so that 1 colón in March 1991 was equivalent to 0.54 colones in January 1988.

### *4.1 Fishing Income and Costs.*

Together, Figures 3 and 4 give a year-by-year view of average daily costs and earnings. Fig. 3 summarizes the key sources of fisher income by species groups (known as "First", "Second", "Cola" and "Bolillo", with the highest price being paid for large "First" class). Fig. 4 shows the proportions of total gross income allocated amongst the various fishing costs and to the fisher's net income.

Fig. 3 indicates that landed values were highest in 1988-89, with 1989-90 being particularly poor and 1990-91 slightly better. However, to fully understand these results, we must note that from historical data, pre-1988 catches appear to have been at least as high as that for year 1 of our study. Hence in reality the 3-year period shown in Fig. 3 depicts a major change in the state of the fishery from what appears to have been shrimp "resource mining" pre-1988 to the present lower level of combined shrimp and fish harvesting.

Two further points should be noted in Figure 3. First, while shrimp catches clearly provide the dominant source of income overall, finfish catches have come to represent nearly 50 % of total income. This reflects an increasing difficulty in locating sufficient shrimp stocks, together with a general increase in fish prices. Second, a notable concern from the conservation perspective is the apparent trend within the "1st class" category toward the harvest of smaller fish.

We turn next to Fig. 4, which indicates the breakdown of average daily gross income into net income and the various cost components -- gasoline, ice, cooperative fees, and other costs. It should be noted that any given sales receipt issued by the cooperative may or may not include any of these costs, depending on whether the fisher in question chose to buy supplies from the cooperative, and whether he or she rented one of the cooperative's boats. The cooperative fee, set at 25 % of landed value, is levied only in the latter case ; this fee can be viewed as a proxy for maintenance and capital costs. To provide as accurate a picture as possible of actual costs and earnings, Fig. 4 is based only on those landings receipts in which a rental fee as well as costs for gasoline and ice were paid.

Fig. 4 shows that costs on average form approximately 40 % of a fisher's gross income. Of these costs, gasoline and cooperative fees dominate. It can also be seen that gasoline constitutes an increasing fraction of total costs, while the reverse is true for cooperative rental fees. (This appears to be due to the fact that in 1990-91, in contrast to earlier years, the cooperative did not consistently collect its fee of 25 % of landed value.)

Trends in gross income for this set of fishers differ somewhat from the combined average shown in Fig. 3, being slightly lower in the first year and significantly higher in the third. Since those fishers included in this set tend to be most closely associated with the cooperative, this result may be due to an increase in the relative quality of those attracted to the cooperative over time.

The daily net income (in January 1988 values) ranges between approximately 500 and 1000 colones. If we assume an average of 15 fishing days per month (allowing for lost time due to heavy rains, high and low tides, and repairs, as well as the "satisficing" effect described below), this amounts to a monthly net income of between 7,500 and 15,000 colones (US$88-176). This range can be compared with official poverty levels (in January 1988 colones) of 22,200 (US$261), 11,500 (severe poverty : US$135) and 7,500 (extreme poverty : US$88).

### *4.2 Variability in Catches and Incomes*

Figure 5 shows the average daily catches of shrimp and finfish, month-by-month between February 1988 and March 1991. It is clear that artisanal fishing in the Gulf of Nicoya is highly cyclical in nature. Shrimp harvesting occurs for nine months of the year, being particularly successful between December and February. During the closed season for shrimp in May-July, fish catches tend to reach their peaks, due to the change in gear to longlines and larger mesh sizes (although fish by-catches have also been significant during the shrimp season, especially in 1990-1991).

Fig. 6 displays the variability in average net income per fishing day across all fishers involved with the cooperative, for the year 1990-1991. While some fishers show a zero net income (indicating that they did not fish, or did not sell to the cooperative, in that particular year), most average between 100 and 1000 colones per trip, and a few obtained very high average returns. This skewed distribution (around an average of 800 colones or US$9.40 per day) is typical of many fisheries. However, it is somewhat lessened here by an important behavioral factor : fishers in Puerto Thiel tend to make their operational decisions on a satisficing basis, in which fishing activity is oriented toward catching "sufficient". This behaviour has significant implications for the pursuit of sustainability, tending as it does to level out the fisher income distribution, thereby easing pressure on the resource and reducing conflict within the community.

## 5. ECONOMIC DIVERSIFICATION

Costa Rica's coastal zone provides an excellent example of the need to combine fishery management and regulation with efforts at economic diversification. Coastal inhabitants are in general among Costa Rica's poorest, receiving relatively little government aid and having relatively few employment alternatives. Pressure on the fishery as "employer of last resort" is enormous.

In an effort to deal with some of the problems facing Pacific fishing communities, the Fishing Community Extension Program of Costa Rica's Universidad Nacional has worked in cooperation with the Canadian nongovernmental organization "Desjardins Society for International Development", in a series of economic diversification projects :

i) The fishing community of Tárcoles is located in the outer part of the Gulf of Nicoya. Its fishery cooperative, which obtains most of its income from selling fresh seafood for export, obtained assistance in forming a small supermarket in the community. One of the fundamental goals of the supermarket has been to provide an employment option for local women. Indeed, the original idea was formulated by female cooperative members, who now administer the store.

ii) In Chacarita, a heavily-populated neighbourhood on the edge of Puntarenas city, the local cooperative is involved in deep-sea fishing, but wishes to diversify its economic base. The cooperative worked with the university and the Desjardins Society to develop a supermarket for the community, which is currently run by the directors of the cooperative.

iii) Nosara is located on the Pacific coast of Costa Rica's Guanacaste province. As in Tárcoles, emphasis in the diversification work was placed on working with the local fishing cooperative to provide employment for women, in this case in a bakery to be run by female members of the cooperative. However, this was never completed due to a variety of problems, ranging from discouragement following the cooperative's failure to develop a deepsea fishing operation, to an earthquake that partially destroyed the bakery during its construction.

iv) As noted earlier, the fourth economic diversification project is located in Puerto Thiel, and reflects the cooperative's desire to develop alternative economic activity which would not affect the fishers' principal activity of fishing and which would provide paid work to those women who wish to diversify from traditional domestic work and child-care.

The diversification project chosen -- one which clearly involved a major departure from the traditional fishing activity of CoopeThiel -- was the development of a tree nursery. This project appeared promising given government encouragement for reforestation in the region, the project's forecast profitability, and its potential to provide formal employment to women in the community. Accordingly, 2.5 ha of land near Puerto Thiel were purchased, on which a small covered workspace with suitable infrastructure was constructed, providing a potential annual production of 185,000 young trees, comprised of commercially viable species such as teak and pochote (genus *Bombacopsis*).

Production levels in the first year of operation were below expectations, due to low survival rates of the trees, and a lack of sufficient training in managing silvicultural activity. Nevertheless, the project is proceeding for a second year of operation, with increasing levels of training and some success in securing wider markets. Hence, the tree nursery continues to provide an alternative source of employment, while demonstrating to Thiel residents the possibility of developing further economic alternatives. The project may also assist in relieving pressure on the fishers to increase their harvesting effort in an attempt to maintain incomes as stock levels decline.

## 6. DISCUSSION

We have suggested that the key objective of fisheries development and management must be the achievement of broad-based sustainability within the fishery system. This idea of fishery "sustainability" has been explored from two perspectives : (1) a conceptual bio-socio-economic framework based on a "Sustainability Triangle" paradigm, and (2) a specific case study relating the ongoing search for sustainability in a Costa Rican fishing community, Puerto Thiel. We have highlighted a view of sustainable development as a multi-faceted process involving the simultaneous pursuit of ecological, socioeconomic, community and institutional sustainability.

What fishery development policy measures are most compatible with the need for fishery sustainability ? In the most common but most difficult context of heavily exploited fisheries -- where the challenge is to improve ecological sustainability through resource rehabilitation, while simultaneously maintaining or improving socioeconomic and community welfare, a dual focus on development and diversification may be optimal, emphasizing :

i) development approaches within the fishery which seek to maximize the benefits flowing directly to fishers, including encouragement of fishing behaviour (such as "satisficing") that tends to have a lower resource impact, a focus on fish sales to local cooperatives rather than to outside buyers, and measures to increase the value added from the harvest -- by improved handling as well as the development of ancillary fishery-related services in the communities affected,

ii) economic diversification outside the fishery sector, to maintain socioeconomic and community sustainability in the face of conservation-oriented management restrictions being implemented within the sector.

Supplementing this "development and diversification" strategy, the Puerto Thiel experience suggests that sustainable fishery development may well be enhanced by an emphasis on integrated policy designed and implemented at the "micro" (community) as well as the "macro" (industry) level. Such approaches are relatively unstudied -- the interdisciplinary research required for their full implementation presents many interesting challenges to practitioners of fishery economics.

# Structure, Constraints and Development Options of Fish Processing and Marketing in Namibia

**Rolf Lasch**

Institute of Agricultural Market Research, Bundesallee 50, 38116 Braunschweig, Germany

ABSTRACT

*1. Potential size of catches*

*The long-term sustainable yield in Namibian waters may be estimated at least around 1.2 million t per year involving 350 000 t of hake, 450 000 t of horse mackerel, 250 000 t of pilchard, and 150 000 t of anchovy, which will place Namibia among the more important fishery nations of the world.*

*2. Production capacities and product mix*

*The fishing industry is concentrated in Walvis Bay, still South African territory. The main items are canned pilchard, fish meal and oil, frozen rock lobster, and only small quantities of white fish. The current canning capacity of 400 000 t of pilchard during a half-year season is much higher than the current level of actual landings.*

*3. Market volume (local, regional and international)*

*As the internal consumption of fish in Namibia will be marginal compared to potential catch, almost the whole catch will have to be exported. The industry will be almost completely dependent on foreign markets and will have to produce according to the specifications of these markets.*

*Namibia may wish to continue its exports to South Africa as it is the dominant neighbouring market, with a relatively developed economy and a population of approximately 30 million. But it is necessary to develop alternative markets in Africa. The major African countries today are Nigeria and the Ivory Coast, but also Egypt, Zaire, Angola and Cameroon import substantial amounts. To what extent other countries in neighbouring southern Africa and in the rest of Africa will become markets for Namibian fish products does, however, depend also on their ability to pay for these imports or whether they can supply Namibia on barter terms with products needed by Namibia.*

*On the world market, there are well established markets for fish meal and oil and Namibia should have no problem in selling its products, which, when fully developed, will represent only a very small part of present total world exports. Namibia will also be able to find export markets for hake and other white fish, primarily as whole fish (headed and gutted) and frozen fillets. It may be more difficult to develop new markets for horse mackerel for human consumption.*

*Likewise, difficult to sell in much larger quantities will probably be canned pilchard. If the pilchard stock is allowed to recover, future catches may reach 250 000 t yearly. If the larger part (60 %) of these catches were canned, production may theoretically reach 10 million cartons a year, which is equal to one fifth of total world production today. It is uncertain that there would be a demand for this additional amount, even if new markets were developed. Even this amount will be substantial by world standards and Namibia will have to adhere to strict quality standards in order to develop and maintain such a share of international markets.*

## 1. INTRODUCTION

The maritime territory off Namibia's coast extends from the border of Angola in the North to the border of South Africa (RSA) in the South, with a coastline of 1 400 km which mainly runs in a north-south direction. This Benguela Current area, an upwelling zone in oceanographic terms, is roughly 150-200 nautical miles wide, overlies the coastal shelf area and represents a sensitive ecosystem. The south-west coast of Africa is one of the maritime areas with the highest worldwide primary production.

Although there are only a small number of fish species in the relatively limited fishing grounds they are present in very large quantities.

The high potential yield of fish resources in Namibia's coastal waters has been known for a long time. Up to independence in 1990, Namibia's unclarified situation in terms of international law has prevented the introduction and international acceptance of the generally acknowledged coastal fishing zone of 200 nautical miles. For many years, therefore, the waters off the Namibian coast have been the only productive and generally accessible fishing grounds for international long-distance trawler fleets. Since 1971 the International Commission for the Southeast Atlantic Fisheries (ICSEAF) has been responsible for the management of fishing in this area.

After the declaration of a 200 m Exclusive Economic Zone (EEZ) and extension of the jurisdiction over the fisheries in the Namibian waters in June 1990, the Government of the Republic of Namibia had to prepare immediately a full scientific resource management for permanent research, stock monitoring and stock assessment just as to establish an effective fisheries administration enabling the control and surveillance of the fishing activities within the 200 mile zone.

## 2. VOLUME OF CATCHES AND STOCK POTENTIAL

Off the coast of Namibia there are in general three major fishing areas, the first two of which have so far been almost exclusively available to the foreign long-distance trawler fleets outside of a coastal zone 13.5 nautical miles wide :

- Hake fishing, primarily carried out by using trawl nets.
- Trawl fishing for pelagic species, primarily carried out using pelagic trawls.
- Inshore fishing for pelagic species, primarily carried out from Walvis Bay using purse-seines inside the 13.5 nautical miles coastal zone.

The **total volume of catch** - sometimes more than 2 million t p.a. during the 1960's - declined markedly during the 1970's and dropped to an average of about 300 000 t in the post-independence period.

The stock biomass of the **hake** has declined steadily. The results of resource surveys on hake confirmed the diagnosis of overexploited resources and estimated total stock biomass for the whole area of 500 000 t, but the main part of fish was small sized and the fishable stock biomass was only 200 000-250 000 t.

In 1990, the Namibian authorities allocated only 55 000 t increasing to 90 000 t in the current year.

The population situation of the biomass of **horse mackerel** is currently characterized by an equilibrium between stock size and exploitation, and the population is not damaged by fishing. The previous biomass estimate made in 1990 showed an imprecise estimate of total biomass in excess of 2 million t. The findings must be interpreted as a confirmation of the good state of this resource.

From the allocated TAC of about 250 000 t one third is reserved for the inshore pelagic fishery.

The preferred target species, which was only fished moderately when fishing in this category began, then excessively and at the same time exclusively, was the **pilchard**. Today, its population is overfished. In the mid-1960's the entire pilchard biomass was still estimated at over 10 million t ; by 1970 this figure had dropped to roughly 1 million t, and since 1977 the level of the adult biomass has only amounted to somewhere between 100 000 and 200 000 t.

Resource surveys on inshore pelagic fish in 1990 gave estimates of pilchard biomass of 240 000 and 750 000 t respectively, which are significantly higher than those obtained in recent prior surveys and might indicate some recovery of the stock. Namibia pursued a policy of regulations of the pilchard fishery largely following the scientific advice. In order to maintain a viable canning industry a seasonal fishing has, however, been allowed, but at a low level with annual landings between 40 000 and 60 000 t in recent years. The allocated TAC's have in cases been exceeded due to the unfortunate by-catch of juvenile pilchard in the anchovy fishery.

The **anchovy** fishery started in 1968 when the pilchard within the catch of pelagic fish began to disappear on a larger scale. This short lived fish had shown large year to year natural fluctuations of yield and stock abundance from the start of the fishery, and annual catches varied between 80 000 t and 350 000 t.

Resource surveys in 1990 gave estimates of biomass of anchovy of around 200 000 t, which represents a very low level for the anchovy.

The **total long-term sustainable yield** may be estimated at least **around 1.2 million t** per year involving 350 000 t of hake, 450 000 t of horse mackerel, 250 000 t of pilchard, and 150 000 t of anchovy, which will, if fully utilized, place Namibia among the more important fishery nations of the world. In the long run the future of the Namibian fishery industry will perhaps lie more in the quantity than the quality of the resources. There are only few high value species (lobster, sole, kingclip etc.) in negligible quantities which may be used for high priced products. The hake is a medium priced fish, while pilchard, horse mackerel and anchovy represent low value species.

## 3. FISHING FLEET, FISH PROCESSING AND MARKETING

### *3.1 Namibian fleet*

The Namibian fleet in 1989 included 164 registered vessels with a tonnage of just under 48 000 BRT. This fleet comprised 39 purse seiners, 53 coastal and deep-sea trawlers, 35 rock lobster boats and 20 line-fisheries vessels. All vessels operating on quotas are now registered in Lüderitz and not as before in Walvis Bay.

### *3.2 Processing industry*

The fish processing industry is concentrated at Walvis Bay which is a fully integrated fishing centre, with modern fish processing and servicing facilities, and rail, road and air connections. The main items produced by the fish processing industry based in Namibia are canned pilchard, fish meal and oil, frozen rock lobster and only small quantities of processed white fish. Until 1977, Namibia was the world's leading supplier of canned pilchard. The entire fishing sector in Namibia was dominated by a small number of South African dominated companies. At present there are 4-5 factories processing pelagic fish, and 3 or 4 processing white fish.

All processing companies for pelagic fish - employing roughly 2 700 workers - are located in Walvis Bay ; together with the production of canned pilchard, fish meal and fish oil they represent the most important subsector of the Namibian fish industry. In 1990 approx. 60 000 t of pilchard were processed into canned fish (4 million boxes) and 190 000 t of pelagic fish processed into fish meal (50 000 t) and fish oil (6 000 t). The current canned fish production capacity of 400 000 t of pilchards during a half-year season is much higher than the current level of actual landings.

At present two factories in Lüderitz, employing a total of 450 workers, carry out lobster processing (primarily whole, deep-frozen lobsters).

*3.3 Products and markets*

The main products of the fishing industry in Namibia are canned pilchard, fish meal, fish oil, rock lobster, and various processed white fish (frozen, smoked, dried).

During the pre-independence period, the South African Government was only allowing exports of **fish meal** outside of the South African Union Agreement (SACUA) after its own demand has been satisfied. Price controls in South Africa did often keep prices lower than the world market, but in recent years Namibian exporters have been negotiating these prices, and obtained a price closer to and even higher than the world market.

Production in South Africa itself has been around 90 000 t annually, increasing to 150 000 t in recent years. Its internal demand has been increasing from around 150 000 t to approximately 240 000 t (1990). At most 20 000 t of the fish meal production (1990 : 50 000 t) is used in Namibia as animal feed.

The whole present production of **fish oil** is exported to the RSA, where the annual consumption of around 40 000 t has been greater than the combined RSA/Namibia production. Fish oil must be refined into edible oils and fats or processed to soaps or other products. The only fish oil refinery in Africa is the Unilever subsidiary in RSA, Lever Brothers. Unilever, which dominates the world market in this product, has an on average taken some 80 % of the Namibian output for processing either in RSA or in UK. Consumption inside Namibia is negligible.

In the past, the main **rock lobster** products were frozen tails, which were mainly exported to the United States, and cooked whole lobsters, mainly for the Japanese market. Since 1980, almost all the production has been cooked whole for the more profitable Japanese market. Small amounts are consumed by the high-income groups and tourists in South Africa and Namibia.

Only a small proportion of **white fish** (especially hake) caught in Namibian waters has been landed in Namibia ; most has been taken by foreign fleets and transported to their home countries. Since independence, an increasing amount of hake caught by Namibian registered trawlers in Namibian waters has been landed and processed in Namibia. In addition, varying volumes of snoek, sole, kingclip, etc. have been landed, and are processed into a variety of products like dried, salted and smoked fish, but the bulk of groundfish is market as frozen fish (frozen blocks, frozen and prepared).

While small quantities are consumed by the upper income groups and some are fed to the contract workers living in municipal or company compounds, most is exported to South Africa and marketed there together with South Africa's own production.

The **horse mackerel** (maasbanker) landed in Namibia is all processed into fish meal and oil, except for some new experiments in canning. The foreign trawlers' catches are taken to their home countries. Some is probably sold to West African countries.

Until 1977 Namibia (and South Africa) was the world's leading supplier of **canned pilchards**. As South Africa itself is a relatively small producer (less than 200 000 cartons/year in 1970-78, increasing to 1.5 million in 1989/90), the bulk of these exports came from Namibia. However, South Africa is also a major consumer and it can be estimated that consumption within the South African Union Agreement (SACUA), which includes the Republic of South Africa, Namibia, Botswana, Lesotho and Swaziland, was in the region of 4 million cartons/year in the mid-1970's, increasing to almost 6 million in the late 1980's. Statistics for the Namibian domestic consumption of fish products are wholly lacking, but less than 10 % of the 5-years-average annual production of roughly 3 million boxes of canned pilchards are sold in Namibia itself at present. The rest is transported to South Africa (and SACUA), whose annual market potential is estimated at 6 million boxes.

At present, very small amounts of fish are consumed in Namibia itself and practically all is exported. Excluding freshwater fish, the total consumption of sea fish and fish products in Namibia amounts to roughly 5 000 t-6 000 t p.a which corresponds to a per capita consumption of 4-4.5 kg.

*3.4 Market capacities - local, regional and international*

As the internal consumption of fish will be marginal compared to potential catch, almost the whole catch will have to be exported in one way or another. The industry will be almost completely dependent on foreign markets as consumers

of its products and it will have to produce according to the specifications of these markets. While some products have a well established international market that can easily absorb an expanded Namibian production, other products may have a more limited market. Also, some markets are highly competitive and require products of a consistently high quality, other markets are accessible for low-priced products only.

### *3.5 Domestic market volume*

Fish is an important food resource and can contribute substantially to increased food self-suffiency in Namibia. Namibia will probably first ensure that there is sufficient fish available to cover the needs of its own population. The present demand in Namibia may well amount to 8 000-10 000 t landed weight during the first few years after independence, increasing in long-term to around 20 000 t with population increases. It is assumed that this will consist mostly of canned pilchard and frozen horse mackerel, perhaps some other demersal species, fresh, frozen, dried, salted, or smoked.

The Namibians may also utilize some more of fish meal in Namibia for feeding their livestock. But, even if this should be developed on a large scale, it will still require only a smaller part of the future Namibian fish meal production.

In the longer run, the consumption patterns may change, switching to a higher proportion of white fish, as well as including more canned pilchards when they become available. Even, if the human consumption of fish will increase to a relatively high rate of 30 kg/capita it would make use of around 3 % of the estimated total potential of 1.2 million t, only and it would not have a large effect on the amount of fish available for export.

### *3.6 African market*

Namibia may wish to continue its exports to South Africa, at the same or even at an increased level. But Namibia may also wish to develop alternative markets and trading patterns in southern Africa and the rest of Africa. The development of new trading patterns will partly be influenced by the institutional arrangements entered into.

Within the members of the Southern Customs Union (SACUA) South Africa is here the dominant market, with a relatively developed economy and a population of approximately 30 million. The other three countries Botswana, Lesotho and Swaziland are less developed economically and have a total population of around 3 million. South Africa today imports yearly some 50 000-100 000 t of fish meal, some body oil and around 3 million cartons of canned fish, which, furthermore, may represent a potential market for Namibian exports.

There are other future markets for Namibian fish products in countries like landlocked Zambia and Zimbabwe, in particular, but also the coastal states of Mozambique and Tanzania may become fish importers from Namibia. As these countries have a combined population of 60 million people, and many are inadequately nourished, Namibian fish could contribute to an improved nutritional standard in these countries. The products required for these countries will be mostly low-priced products that can be easily transported and stored, such as dried, salted and smoked fish or canned fish. Possibly some frozen fish can also be exported. To what extent other countries in neighbouring southern Africa and in the rest of Africa will become markets for Namibian fish products does, however, depend also on their ability to pay for these imports or wether they can supply Namibia on barter terms with products needed by Namibia. Exports to these countries will also depend on improved transport and communications.

Informations on the present fish imports of these countries is incomplete but imports are generally rather low. It is very difficult to estimate the possible scale of future Namibian fish exports to other African countries but is unlikely that it can become substantial during the next years.

It should, nevertheless, be possible to develop major Namibian markets in other African countries in the future, as their imports today include such products as frozen horse mackerel, dried and salted white fish and canned sardines. The major African countries today are Nigeria and the Ivory Coast, but also Egypt, Zaire, Angola and Cameroon import substantial amounts.

### *3.7 World market*

There are well established markets for fish meal and oil and Namibia should have no problem in selling its produce, which, when fully developed, will represent only a very small part of present total world exports.

Namibia will also be able to find export markets for hake and other white fish, primarily as whole fish (headed and gutted) and frozen fillets.

It may be more difficult to develop new markets for horse mackerel for human consumption. Increasing amounts are, however, consumed in African countries as noted above.

Likewise, difficult to sell in much larger quantities will probably be canned pilchard. If the pilchard stock is allowed to recover, as assumed in this report, future catches may reach 250 000 t yearly. If the larger part (60 %) of these catches were canned, production may theoretically reach 10 million cartons a year, which is equal to one fifth of total world production today. It is uncertain that there would be a demand for this additional amount, even if new markets were developed. Even this amount will be substantial by world standards and Namibia will have to adhere to strict quality standards in order to develop and maintain such a share of international markets.

## 4. FUTURE STRUCTURE OF THE FISHING INDUSTRY

In Namibia, except Walvis Bay, Lüderitz and sport fishing, particularly in Swakopmund, there are no other permanent settlements along the coast where fishing is undertaken or combined with agriculture as the coast itself is a desert along its entire length. Therefore, small-scale fisheries to a great extent will not be viable ; in the situation, where fish is plentiful, the major fisheries have to be more industrially organized. Small-scale operations may not be profitable at all.

### *4.1 Inshore pelagic fisheries*

For pilchard and anchovy, no realistic alternative to purse seining exists and this method of fishing is probably also superior one for horse mackerel fishing in the shallow inshore waters. Both during the medium- and the long-term periods there will be a fish meal and oil industry based on anchovy and horse mackerel.

### *4.2 Offshore trawl fisheries*

Trawling is probably the only rational fishing method for exploiting the hake resources. Assuming that Namibia in the long run will try to develop her own land-based processing industry, the vessels needed for hake fishing will not be large freezer factory trawlers of the types and sizes until independence fishing off Namibia. What is required are trawl fishing vessels capable of efficient operation in the required depth range and with suitable facilities and storage systems for handling and transportation the fish back to Namibian ports in prime condition.

The extent to which freezing facilities need to be extended in the case of white fish decisively depends inter alia on whether preference is given to land or sea freezing.

The resource base, the scarcity of natural harbours, the absence of a coastal artisanal fishing sector, and the absence of an important domestic fish market, all point in the direction of industrial processing of the resources. Sustained yields of up to 250 000 t of pilchard and 350 000 t of hake should without doubt support industrial food processing methods and modern mass production technologies, regardless of the activity being carried out at sea or on land. This will tend to a vertically integrated organization scheme (same companies owning/managing boats, plants and marketing) in the future fishing industry.

The precise product mix will depend on a variety of factors too complex to predict with any certainty. The type of fish is the most obvious restriction : hake is best suited to processed frozen products, snoek to drying and salting, pilchard to canning, anchovy only to fish meal. The greatest flexibility lies with horse mackerel, which may be reduced or frozen.

The main products from a fully developed Namibian fish processing industry will be : fish meal, fish oil, canned pilchards, frozen hake fillets, round frozen hake, horse mackerel and other pelagic and demersal species.

In the present market situation there is a demand for all these products, although it may be easier to sell some products than others. Marketing of fish meal and fish oil should not be difficult. On the other hand, marketing frozen horse

mackerel in blocks, taking costs of transport into consideration, may be more difficult. For certain products Namibia will have a considerable potential. This will especially be the case in canned products based on pilchard. It is not likely that Namibia can utilize its full potential of pilchard for canned products only. The alternatives are fish meal and fish oil. The various frozen products of the demersal species will never take a big share of the world market.

The existing processing capacity will be sufficient to handle the estimated short- and medium-term pelagic catches. White fish processing presents far greater difficulties. The capacities are well below the maximum medium-term projections for horse mackerel (frozen blocks) and hake (headed & gutted, fillets and prepared foods) respectively.

Plant operation basing on a single species is entirely dependent on its fluctuations in availability. Pilchard may prove to be the only species for which large-scale canning is commercially viable ; but horse mackerel may be marketed both frozen as wet fish and reduced to meal and oil. Since anchovy, the staple supply to the reduction plants, is far more volatile than hake, the main white fish species, the principal advantage of fleet flexibility would be to enable the former to turn to horse mackerel whenever anchovy was in short supply.

A national Namibian fishery sector will have to establish fleet and processing structures of largely the same types which exist today. In addition, to reap the full benefit of a long-term potential they will have to extend the white fish sector considerably both at sea and on shore.

The fact that both pilchard and horse mackerel may be reduced to meal and oil give Namibian investment planning flexibility to adjust to changing market conditions.

## 5. FISHERY POLICY OBJECTIVES

### *5.1 The role of fisheries in the national economy*

During the 1960's and early 1970's the fishery sector was a relatively important part on the Namibian total economy. Fishery products represented close to 25 % of total exports in the mid-1970's and the fish processing industry was the most important manufacturing industry. Total employment in the sector was up to 11 000 workers and fishermen.

With the collapse of the pelagic fishing in the Namibian Sea and the closure of several processing plants the importance of the fishery sector was drastically reduced. In the late 1980's the gross value of output from the fishery sector can be estimated at around R 280 million. Fish products thus represented between 5 and 10 % of total exports and the sector contributed around 3 to 4 % of GDP. Total sector employment could be estimated at around 4 000-5 000 persons during the season, but only a few thousand on a more permanent basis. Many are employed on seasonal contracts only. Whilst the shore based labour force consists mainly of migrant workers from northern Namibia, few non-white workers have been employed in responsible positions either at sea or ashore.

The offshore trawl fisheries never contributed more than insignificant amounts (some servicing of fleets in Walvis Bay) to the Namibian economy. The landed value of the annual catches in the late 1980's was around R 500 million and these values could be substantially increased by processing in Namibia.

The Namibian Government is faced with a variety of options with respect to objectives of fisheries development :

- Optimal Management of the renewable natural resources
- Increasing domestic food supply
- Creation of employment
- Contribution to national income
- Earning of foreign exchange through exports
- Increasing influence and participation of Namibians in the economy

## 6. SHORT- AND MEDIUM - TERM TASKS OF FISHERY POLICY

### *6.1 Research and surveillance*

The volatile nature of the aquatic environment, its biological processes and fluctuating production levels necessitate a permanent research and the introduction of measures aimed at the recovery of the overfished populations in order to ensure an optimal utilization of the resources in the short, medium and long-term.

This is basic prerequisite for fishery management and its decisions regarding protection, conservation and utilization of the stocks. Considering the complexity of the research field and the technology required, no quality research is possible without the very basic facilities such as an adequate research vessel, specialized equipment and well-qualified research personnel.

The setting up of an effective inspection service to supervise fishing legislation within the 200 nautical mile zone, which encompasses an area of almost 500 000 sq. km is not finished until today. Furthermore, this requires several vessels, perhaps aircraft too, and definitely a modern communications system.

### *6.2 Administrative provisions*

Prior to 1984 the administration of the fisheries sector of Namibia formed part of the South West Africa Administration based in the Republic of South Africa. By that time control of the sector was partly transferred to the Administrator General based in Windhoek. In 1986 measures to Namibianise the inshore pelagic fishing industry were introduced by the administration in Windhoek. The stated purpose of these policies was to increase Namibian participation in the fishery sector as workers, managers and owners, to increase income accruing to Namibia from the fisheries, and to ensure that part of the profits were reinvested in Namibia.

These measures led all companies to establish registered offices in Windhoek or Lüderitz, and to sell part of their shares to Namibian residents. Also, all vessels fishing under licence from the Windhoek administration were entered in a registry of fishing vessels kept at Lüderitz.

These arrangements were maintained by the Namibian Government in the first years after independence. In principle under this system the fish caught in Namibian waters remain the property of the Namibian registered companies that "rent" the facilities in Walvis Bay for processing, until the finished products are sold through Namibian-registered marketing companies. Both companies and vessels registered in Namibia are taxed by Namibia, while only the value of processing is taxable in Walvis Bay. Partly as a result of these measures (but also because of good catches), the revenue collected from the fisheries sector increased.

According to provisions implemented by the previous Windhoek Administration in 1986, no commercial catching and/or processing of Namibian fish could take place without a concession from the authorities. Under this system a concession was granted for a period of 7 years. A fishing vessel can only be licensed to fish through individuals or companies possessing a concession. As a result of a Cabinet Resolution of January, 1991, all present concessionaires and licence holders in the fishing industry must apply anew.

Before independence, quotas were allocated to concessionaires on the basis of a proposal from the Directorate of Sea Fisheries to the Administer General. The proposal for a quota allocation was given according to a set of guidelines taking into consideration such factors as :

(i) The special expertise and experience of and/or standard or research done by the applicant as regards the resource,

(ii) the applicant's compliance with legislation and regulations,

(iii) the extent of direct interest in investing or opportunity for direct participation for bona fide Namibian residents to invest in the applicant's enterprise,

(iv) the applicant's investment in the fishing industry of Namibia,

(v) the extent to which the applicant has invested his profit/tax deduction in economically productive industries other than the fishing industry in Namibia, and the nature of such investments.

Since independence, the quotas have been decided upon by the Ministry of Agriculture, Fisheries, Water and Rural Development, and afterwards by the Ministry of Fisheries and Marine Resources. A quota system for horse mackerel was introduced in addition to those for hake, pilchard and rock lobster.

In June, 1990, a new quota levy was introduced for the catching of hake and horse mackerel, only. The basic idea of the system is to ensure income to the Namibian Government from the fish resources and at the same time give incentives for Namibianization of the industry. A rebate is therefore allowed depending on the extent of Namibian shareholding, processing, and employment. In addition, a smaller research fee is levied on all fish catches.

The main objective for licence and quota system is to limit and control fishing for resource management purposes. In addition, the quota allocation system has more recently been used in order to increase Namibianization of the sector. While the main purpose of the quota (and research) levy is to increase Government incomes from the exploitation of a common natural resource, a system of rebates has been introduced in order to give more incentives to Namibianization.

This system regarding licensing of processing plants, the setting of overall quotas and allocation of these among concessionaires based on a number of criteria, and the new system of quota levies and rebates was very difficult to operationalise. The system of allocating yearly quotas on the basis of various performance criteria is complicated to operate, and may not lead to the intended results. The objective of stimulating Namibianization may therefore instead be obtained through exercising preferences in giving or renewing licences, and economic incentives through levies and rebates. While keeping with the objectives of these measures, improvements and adjustments were necessary in order to make them more effective, less complicated to implement, and reduce unintended effects.

It is common practice in many countries to put the main emphasis of fishing regulation on the licensing of vessels and to allocate fishing quotas only to owners of licensed fishing vessels. This create a clear link between fishing efforts and the regulation of fishing, and gives all vessel owners an equal opportunity to obtain quotas. However, there will be a need to regulate carefully the number of vessels licensed, and to distinguish between Namibian, foreign and "mixed"-vessels, e.g. having a mixed Namibian/foreign crew and mixed ownership. Preference when applying for licences should first be given to Namibian vessels. Secondly, "mixed" vessels may be considered, provided that the number of Namibian vessels is not sufficient. Only if the total number of Namibian-registered vessels (including "mixed" boats) is not sufficient, will there be room for chartered or other foreign vessels, on a year-to-year basis. A licence to a "Namibian vessel" may be given on a long-term basis, possibly for a period of approximately 10 years, renewable. "Mixed vessels" may be licensed for a period of 5 years, renewable if there are not sufficient "Namibian vessels". Furthermore, a fishing licence (concession) will only be given to companies, individuals or groups owning a vessel, and the licence will be linked to a particular vessel. All new applicants must therefore either own a vessel or present a clear plan on how to acquire one.

If the above system of licensing is introduced, it may be reasonable to allocate the yearly fishing quotas among the concessionaires having "Namibian" or "mixed" vessels on the basis of certain technical characteristics of the vessel such as size.

In principle there should be no need to control or licence fish processing plants, as this could be left to the free market. Furthermore, there will no longer be a need for allocating yearly processing quotas among the plants. The present double quota system (for pilchard) may represent an additional check and control, but has not proven effective. At the same time it limits competition among companies and boatowners. It would be preferable if fishing quotas are allocated to vessel owners, so that individual boatowners will be free to deliver to any processing company.

### *6.3 General considerations in granting fishing rights*

The granting of fishing rights and the annual allocation of quotas, i.e., the differential shares of the Total Allowable Catch (TAC) should be based on the following considerations :

(i) Fishing vessel, registered and owned locally and flying the Namibian flag ;

(ii) Investment and participation opportunities afforded to Namibians (equity participation)

(iii) Level of fish processing in land-based plants promoting value-adding ;

(iv) Creation of jobs opportunities ;

(v) Establishing wage systems for employees which are partially independent on the quantities caught or processed ;

(vi) Training of and housing, medical and pension schemes for employees ;

(vii) Investment of profits in Namibia.

A concession (fishing right) should be a medium or long-term right to catch fish and the duration should be sufficient as to allow time for a reasonable planning. Investment in the marine fishery is usually highly capital intensive and need an acceptable assurance of protection of the rights granted to him for at least a reasonable period of time (5-10 years).

### *6.4 Size of quotas*

The size of quotas should on the one hand enable a concessionaire to be economically viable in the specific fishery sector and should on the other hand avoid mere speculation with the fishing rights without any intention to participate in the fishing sector. The fishing rights (and quotas) should be allocated only to such persons which are willing and able to start catching (and processing) immediately, at least a substantial share of their quota.

The size of the TAC-shares will differ in the different sub-sectors of the fishing industries.

### *6.5 Levies*

It is becoming more common in many countries to charge a "resource fee" for the use of natural resources. It is also a fully acceptable practice in fisheries to charge a licence fee for foreign fishing. Also for national fishing, the resource represents a value. Since taxing may sometimes prove difficult, a levy will be a more effective form of taxation.

In the past a special quota levy was charged in respect of hake and horse mackerel only, while a smaller research fee was levied on all catches. For the quota levies, rebates were given on the basis of whether the fish was processed on land or not ; for employment of Namibian fishermen on the vessels ; and for ownership participation by Namibians. This system for assessing these factors was difficult to control and in particular the definition of land processing was incomplete, and may lead to distortions.

The new established system is now using simpler criteria in order to give economic incentives to Namibianization of the fishing operations : differential levies for Namibian, "mixed" and foreign vessels, as described above. While the differentiation between national and foreign vessels is quite common also in other countries, the "mixed" category is innovative, but could well be justified in the Namibian situation. Now, there is a model which includes a basic levy for Namibian ships and a surcharge for "mixed" and foreign boats of 50 respectively 100 %.

Furthermore, there was a rebate for land processing, with the objective of stimulating employment in Namibia. This rebate was mainly relevant for hake and other white fish, since for the small pelagic (pilchards and anchovies) there is no real alternative to land processing (canning and reduction). For horse mackerel there may exist alternatives, but today this resource is so abundant that there is no effective quota for the Namibian based inshore vessels. In any case it may be more important to stimulate whole freezing of horse mackerel, which produces a more valuable product, than reduction to fish meal and oil, regardless of whether this is land-based or not.

For hake and other white fish, however, there is a justification to stimulate processing on land, especially if this involves labour-intensive manual filleting. At present most of the catches are frozen (headed and gutted) on board the freezer-trawlers, and exported without further processing. From a Namibian point of view, it will be more beneficial if processing is undertaken on shore, and a rebate on the levy is therefore one option for stimulating this.

For pilchard it might be important to stimulate further the delivery of the catches for canning which is more employment creating than reduction. One possibility is therefore to establish a higher levy for pilchard, to make it less economical to deliver it for reduction.

Now, the current trawling quota levies are :

| | | | Rands/ton |
|---|---|---|---|
| Hake | | Basic levy | 400 |
| | Namibian vessels | | 400 |
| | "Mixed" vessels | + 50 % | 600 |
| | Foreign vessels | + 100 % | 800 |
| Horse mackerel | | Basic levy | 50 |
| | Namibian vessels | | 50 |
| | "Mixed" vessels | + 50 % | 75 |
| | Foreign vessels | +100 % | 100 |

On hake there is a rebate of R 200 per ton if the fish is landed for filleting, but there are no rebates on horse mackerel.

Pelagic quota levies are :

| | | | Rands/ton |
|---|---|---|---|
| Pilchard | | Basic levy | 100 |
| | Namibian vessels | | 100 |
| | "Mixed" vessels | + 50 % | 150 |

No foreign flag boats are allowed and there are no rebates on the levies.

The basic level of the levies should be adjusted from time to time, taking in account the value of the fish, but also factors regarding catch rates, cost structures, and the profitability of fishing operations. In most cases the basic level will vary between 5 and 15 % of the first-hand value. The system of rebates and surcharges should be more permanent.

In principle, all quota-regulated fish should be covered by a levy system, while species for which there is free fishing should not require any levy.

The levy must be charged on the quotas allocated, without regard to the volume of fish actually caught, i.e. they are to be paid every month during the season, whether or not fish has been caught. This will therefore not provide any additional incentive to underreporting. It will also give concessionaires an incentive not to apply for higher quotas than they actually catch.

The granting of licences to foreign vessels to fish the "surplus" quantities which cannot yet be fished by the Namibian fleet could be linked with rights of access to foreign markets (e.g. Spain, Portugal) for Namibian fisheries products ; a granting of licences should at any rate be linked with the training and promotion of Namibian fishermen and scientific personnel.

## 7. OUTLOOK ON THE FUTURE NAMIBIAN FISHING INDUSTRY

With proper supervision of both inshore and deep-sea fisheries, comprehensive conservation, population research and reinvestment in trawlers and processing factories, Namibia could again sustain one of the world's most important fishing industries. Namibian fish, since it is widely available and easily stored, could supply major part of the nation's protein requirements. Fish meal is a valuable feed for stock farming. Since internal consumption would probably account for a relatively small proportion of the total catch, a fully developed industry could be one of Namibia's major export earners.

# The Welfare Impact of Improved Boat Modernisation Schemes (IBMS) in Pemalang Regency, Central Java - Indonesia

**Indah Susilowati** *

Faculty of Economics Diponegoro University, Jl. Erlangga Tengah 17, Semarang 52241, Indonesia

ABSTRACT

*The open market fish model was developed to investigate the factors affecting supply and demand of fish in Pemalang Regency. Furthermore, based on the estimated supply and demand functions the Producers Surplus (PS) and Consumers Surplus (CS) as a welfare measurement of IBMS were estimated. The findings indicate that the IBMS was ineffective to enhance the welfare of Pemalang Society.*

## 1. INTRODUCTION

Agriculture plays an important role in the Indonesian economy. It contributed 24.09 percent to Gross Domestic Product (GDP) and 55.80 percent to employment in 1988 (BPS, 1989). Among the agricultural sub-sectors, the fishery contributed 1.70 percent of the total GDP. Nonetheless the number of people involved in the fisheries sector reached 1.3 million people excluding those engage in the processing plant in 1986 (Martosubroto, 1987).

Fish is the primary source of animal protein. It provides 67 percent of animal protein of the total Indonesian diet, whereas meat, milk and egg contribute 21, 7, and 5 percent respectively (Naamin, 1987). Moreover, it is relatively cheaper compared to other source of animal protein. In capture fisheries, the general impact of government credit schemes has been the modernisation of fishing fleets. To commensurate with the modernisation efforts to enhance production and productivity of traditional fishery, some of the alternatives taken by the Indonesian government were : the introduction of boat modernisation schemes, fishing gear improvement and diversification of multi-gear usage to ensure the continuity of operation throughout year. In consonance to the call to modernize the fishery sector in the country, the fishery authority

* This paper is a part of the master thesis of the author.

I would like to ackowledge Dr. Nik Mustapha Raja Abdullah, at the Faculty of Economics and Management, Universiti Pertanian Malaysia for his useful comments.

of Pemalang Regency, the study area of the research, has chosen the same alternatives as laid out by the central authority, namely through the Improved Boat Modernisation Schemes (IBMS). This programme basically involves providing fishermen with the fishing credit schemes. It is expected that production and productivity will be increased and the fishery industrialization may be achieved much faster.

In Pemalang Regency, the provisions of IBMS which started in 1982, are handed to the fishermen in the form of a package through credit schemes. The report of PELITA IV of Pemalang Fishery Office [1989] observed that the IBMS programme has been working very well since then. This may be due to the fact that fishermen in Pemalang are relatively more responsive to new technologies compared to fishermen in other regions in Central Java. To some the programme is treated as an upgrading of the existing fishing method and to date IBMS has been widely diffused among the fishermen in this Regency (Annual Report of Fishery Office, 1989).

## 2. STATEMENT OF THE RESEACH PROBLEMS

Fish serves as an important source of protein to Indonesian people (providing 67 percent of total animal protein to the Indonesian diet). The current per capita fish consumption in Pemalang Regency of 12.10 kg per year however is still below the national target of 18 kg. Subsequently, to achieve the national target per capita fish consumption has to be increased by 48.76 percent.

It was reported that the minimum requirement for Indonesia averages about 29.5 kg fish per capita per year (Monintja, 1982). Therefore the attainment of high level of sufficiency in fish production has become a major agenda in the development policy. Consequently, a range of programmes to promote increase fish production have been implemented, and one of them is the IBMS.

Improvement of the fishery sub-sector in Pemalang Regency is important since it is characterized by a relatively high level of poverty. In addition, there are about 18,149 fishermen consisting of 56.53 percent marine fishermen and 43.47 percent in inland fishermen in Pemalang Regency. The marine fishermen are basically small-scale operators with low production and productivity (Yamamoto, 1987). Reduction of poverty among marine fishermen has therefore become an important agenda in the development planning of the Pemalang Regency. Invariably, the main objective of poverty reduction policy is to increase the income of fishermen through higher productivity.

Being small-scale fishermen constrained by capital, skill and traditional psychology (Budiono, 1974), it is difficult to improve their productivity. Furthermore, their operations are limited by the traditional technology (gears and boat mechanic) and concentrated in the nearshore fishing grounds which are mostly overexploited. Concomitantly, the production and productivity are not enhanced.

The offshore pelagic and demersal resources offer the best hope for increasing marine production. To reach these fishing grounds, boats must be provided with engines and appropriate equipment (Bailey, 1987). In compliance with these suggestions, the government has issued the Improved Boat Modernisation Schemes (IBMS).

The IBMS is expected to enhance the income, productivity and employment opportunities of fishermen, and at the same time, it also aims at providing sufficient nutrition to the society. Several questions then arise : Is the economic performance of IBMS commensurate with the objectives envisaged ? What is the overall impact of the IBMS programme ? What are the welfare gains to fishermen and consumers ? Does it increase net social welfare or otherwise ? These are some of the questions which have not been fully answered and which need immediate answers.

Unfortunately, very little research work have been conducted in this field, therefore it is a timely attempt in this study to obtain a deeper understanding of the impact of IBMS on the society as a whole.

## 3. OBJECTIVES OF THE STUDY

Overall, this study examined the net welfare impact resulting from the IBMS programme in Pemalang Regency. The scope of this study can be narrowed down as follows : firstly, it examines factors affecting the structural supply and

demand of fish pre-IBMS and post-IMBS. This is followed by the estimation of the elasticity of structural parameters of the supply and demand of fish. Finally, this study attempted to evaluate the distribution of welfare gains/ losses and a change of the net social welfare/ losses that resulted from the IBMS implementation.

## 4. PREVIOUS STUDIES

There are several approaches to estimate the welfare impact and they include the utility approach and /or the surplus approach. This study will adopt the later approach. The surplus concept, is relatively closer to the market situation which in general can be represented by producers and consumers surplus. The estimation of welfare impact involves estimating the supply and demand functions as well as the interaction between the two.

Posadas (1985) carried out a research on fish consumption in Iloilo, Philippines using OLS as an analytical tool of multiple regression. Meanwhile, Yeoh (1975) employed OLS, 2SLS, and 3SLS estimating techniques in evaluating the net welfare of producers and consumers and market intermediaries in the frozen Concentrate Orange Juice (FCOJ) in Florida. Furthermore, the similar technique was adapted to measure welfare changes that result from changes in regulation on trawler fisheries in the Gulf of Thailand (Janekarnkij, 1986). The same technique which accordingly modified also be used to estimate the welfare gains/ losses from fishing modernisation schemes (Susilowati, 1991). Moreover, the later technique will be adopted in this paper and will be discussed in the following sections.

The estimation techniques mentioned above have also been commonly used in other fields to measure the welfare impact of the imposition of various types of policies (Adam *et al.* (1977), Frech *et al.* (1980), Olson *et al.* (1984), Foster *et al.* (1986), and Khalid (1989)).

## 5. METHODOLOGY

In this section the welfare of fishermen (as producers) and fish consumers in the Pemalang Regency will be estimated. The net social benefit of Improved Boat Motorization Schemes (IBMS) was evaluated using Producers' Surplus (PS) and Consumers' Surplus (CS) measurements. These surplus estimations were obtained from the structural equations of supply and demand functions of fish. The welfare impact of a change in supply of fish in the market as a consequence of the implementation of IBMS policy was then examined.

The fish consumption pattern did not fluctuate very much during the period (1976-1990) covered in this study. Therefore, the demand of fish was assumed to be quite stable. Only the supply of fish has a direct effect from change in technology.

Several assumptions are made in this study : (1) the fisheries is assumed to be operating in a perfectly competitive market, wherein many producers as well as consumers in the fish market and boat operators are profit maximizers ; (2) there exists open-access fisheries ; (3) only path independence analysis where a change in single price is allowed, and finally (4) there is constant marginal utility of money (change of gains or loss of PS is equivalent to the change of CS).

## 6. MODEL CONSTRUCTION AND DATA REQUIREMENTS

### *6.1 Model Construction*

The quantities of fish supplied and demanded are related to the same price of fish in the market. The determination of the market price of fish stipulates the jointly dependent variables between the quantities of fish supplied and demanded in the open market. Therefore, a simultaneous equation model is developed to examine the factors affecting both supply and demand of fish in the market.

Data for the variables in the best fit model were first standardized into the deviation transformation using the following formula :

$$X_{ij}^{ST} = (X_{ij} - AX_{ij}) / \{ {}^{1}E(X_{ij}-AX_{ij})^2 \} \quad (1)$$

where :

$X_{ij}^{ST}$ = Standardized variable of $X_{ij}$

$AX_{ij}$ = Arithmetic mean of $X_{ij}$

This transformation was done to eliminate the econometric problem such as multicollinearity which may occur in the model. Thereafter, the models employed for the empirical study are given below.

(1) Supply : LTIQS = f(LTPFI,LTIFE,LCP1,$LTIQS_1$) (2)

(2) Demand : LTIQD = f(LTPFI,LTIPS,$LTPFI_1$ ,$LTIQD_1$,LTIY) (3)

(3) Identity : LTIQS = LTIQD (4)

The definition of variables after standardisation is given in Table 1. Furthermore, this model is also used in the welfare estimation in this study.

Equation [2] expresses the behaviour of fish production which is supplied in the market. The quantity of fish supplied (LTIQS) is hypothesized to be a function of current price of fish (LTPFI), fishing effort (LTIFE), probability to catch fish (LCP1), and the quantity of fish caught in the previous period ($LTIQS_1$). While, the quantity of fish demanded (LTIQD) is hypothesized to be a function of its own price (LTPFI), price of other commodities which can either be a substitute or complement (LTIPS), lagged own price ($LTPFI_1$), lagged quantity of fish demanded ($LTIQD_1$ ), and consumers' income (LTIY).

The model used in this study comprises of three equations, two of which are stochastic and one is an identity equation. In this case, the model consists of 9 variables of which 3 variables are endogenous and 6 variables are predetermined/ exogenous. The LTIQS, LTIQD, and LTPFI as endogenous variables are interdependent (jointly dependent).

### *6.2 Data Requirements*

Quarterly data on fish production, fish consumption, prices of fish, fishing effort, probability to catch fish, price of substitute/ complementary goods and average income before and after IBMS were gathered from the statistics and report from the Pemalang and Central Java fishery and Indonesian Statistical Bureau (BPS) offices for estimation purposes. The relevant data before IBMS started from the second quarter of 1976 to the fourth quarter of 1981, while for the after the IBMS covered the period from the first quarter of 1982 to the second quarter of 1990. These data were aggregated by Geometric Index (GI) method as discussed by Hutabarat (1987).

## 7. ESTIMATION PROCEDURES AND STATISTICAL CONSIDERATION

### *7.1 Estimation Procedures*

#### 7.1.1 Estimation of Structural Supply and Demand Models

The Two Stage Least Square (2SLS) technique using single equation approach with Principle Component (PC), was used to develop structural supply and demand models before and after IBMS.

In utilizing the simultaneous equation method, the model was first checked for identification problem. It was found to be overidentified. Subsequently, the Chow test proved that the estimated relationships before and after IBMS were significantly different. Therefore the sample was divided into before ($N_1$=22) and after ($N_2$=34). The test of

autocorrelation using the Run test showed the absence of autocorrelation problem in the supply and demand models. However, multicollinearity was discovered after diagnosing the correlation coefficient matrix of the demand model. Eventually, the multicollinearity problem was mitigated by estimating the 2SLS with PC method. Lastly, the validity for forecasting performance of the estimated best fit model was examined using Theil's inequality coefficient (U) and Root Mean Square (RMS) prediction. The estimated models were found to have good predictive ability, either in terms of overall models, or equation-wise.

The model was estimated using the data in terms of nominal values (original data), deflated values, and indexed values which were in linear and log-linear forms. However, it was found that the indexed data in the log-linear forms gave the better fit than the others.

### 7.1.2 Determination of Welfare

By simplifying the structural supply and demand functions derived from the best fit model to the form of quantity-price relationships {Q=f(P)}, the derivation of the equilibrium price and quantity in the market can be derived as follows :

$$\text{Supply} : QS = a_0 + a_1 P \quad (1)$$

$$\text{Demand} : QD = b_0 - b_1 P \quad (2)$$

where :

QS, QD = quantity supplied and demanded at price P

$a_0$ , $b_0$ = intercept for supply and demand functions

$a_1$, $b_1$ = slope of supply and demand functions.

$a_1 \geq 0$ and $b_1 \leq 0$

At equilibrium point, QS = QD and the values of equilibrium price (P*) and quantity (Q*) will be :

$$P^* = \frac{b_0 - a_0}{a_1 + b_1}$$

$$Q^* = \frac{a_1 b_0 - a_0 b_1}{a_1 + b_1}$$

In order to calculate the PS and CS, the supply and demand functions should be in the inverse form of P = f (Q) as follows :

$$\text{Supply} : P = -\frac{a_0}{a_1} + \frac{QS}{a_1} \quad (1)$$

$$\text{Demand} : P = \frac{b_0}{b_1} - \frac{QD}{b_1} \quad (2)$$

The supply and demand functions in this model were not in the linear form, therefore, integral calculus approach to compute PS and CS seems to be the much more appropriate. The welfare derived from PS and CS which is accruing to society is given by the NSW which is equal to PS plus CS :

$$NSW = PS + CS$$

(1) When $a_0 \geq 0$

$$NSW = P^* Q^* - \int_{Q=0}^{Q=Q^*} (Q_S)\, dQ_S + \int_{Q=0}^{Q=Q^*} f(Q_D)\, dQ_D - P^* Q^*$$

(2) When $a_0 < 0$

$$NSW = \int_{P=0}^{P=P^*} f(P_S)\, dP_S + \int_{Q=0}^{Q=Q^*} f(Q_D)\, dQ_D - P^* Q^*$$

However, the estimated structural supply function has a $_0 < 0$, and consequently the later formula will be utilized to compute the NSW.

### 7.1.3 Statistical Consideration

Hypothesis testing in 2SLS is complicated by the unknown distributions. This causes the normal t- and F-tests as well as the coefficient of determination ($R^2$) to be invalid because they lack empirical content in simultaneous model. The F-test from the analysis of variance table is also invalid (White *et al.*, 1989). Therefore, in this study the standard error of the estimated parameter was used as the basis for hypothesis testing. Accordingly, if the respective coefficient is greater than half of its standard error value, the null hypothesis (estimated coefficient of parameter is not significantly different from zero) will be rejected. Based on this criterion, it can be concluded that there is a significant relationship between the independent and its dependent variables, *ceteris paribus*. Moreover, the statistical result which has highest numbers of significant variables in the equation, the smallest standard error, and coincidence of its parameters' signs with a priori expectations could be considered as the best fit model.

## 8. RESULTS AND DISCUSSION

The statistical results indicated that the significant level of estimated parameters in the supply were fairly good as shown in Table 2. All variables specified in the model obtained the expected signs for both before and after IBMS. For the supply model, the respective coefficients of all variables are greater than half of its standard error except for fishing effort (LTIFE) and the probability to catch fish (LCP1) before and after IBMS. The supply model was positively sloped with respect to its own price which is consistent with the classical economic theory. This implies that fish supply increases as factor input is added to the production process, *ceteris paribus*. However, the rate of increase in fish production which is brought about by additional input is diminishing.

The 2SLS with PC improved the estimated demand model (using conventional method) in that the sign of the price of fish variable (LTPFI) was as expected while many other variables became more significant. The negative relationship between price of fish and its quantity demanded are also consistent with the economic theory for both before and after IBMS periods as explained by Table 3. The estimated coefficients of all variables are greater than half of its standard errors except for the intercept before and after IBMS and the lagged of quantity supply before IBMS.

The estimation results indicate that The LTIPS and LTIY formed the major determinants of the quantity of fish demanded throughout the study period. The elasticity of the fish demanded with respect to its own price is greater (-0.676) at post-IBMS than at pre-IBMS (-0.295). Implicitly, consumer will tend to consume more fish when the price of fish decrease during the post-IBMS than during pre-IBMS. On the contrary, when the price of fish increases, consumers will decrease their consumption of fish by a greater amount at post-IBMS than at pre-IBMS.

The signs of the estimated coefficient for other commodities (substitutes and complements) were positive. This indicates that the other commodities in this demand model are substitute goods. Lastly, the income elasticity of demand for fish tend to be more elastic before IBMS (0.740) than after IBMS (0.580). This observation indicates that fish is not capturing consumers dollars when income increases. As income increases people tend to spend more on non food items such as clothing, housing, and others. This in fact supported the belief that fish is indeed inferior compared to other goods.

The welfare analysis showed that the IBMS programme was ineffective to augment fish production in Pemalang Regency as indicated in Table 4. The IBMS programme has caused the welfare loss to society amounting to about 142.86 percent from the original situation (pre-IBMS). The larger portion of loss (about two-third) was incurred by consumers while the remainder loss was suffered by producers. The results revealed that consumers consistently lose while the producers always gain but in decreasing amount.

## 9. CONCLUSIONS AND POLICY IMPLICATIONS

### *9.1 Conclusions*

All variables specified in the supply model had expected signs and significant except for the fishing effort and the probability to catch fish. As expected the supply function was found to be positively related with respect to its own price.

At the same time, the demand model had negatively slope with respect to its own price and all of the signs of estimated parameters were consistent with the theory except for the lagged price of fish variable.

The welfare analysis showed that the IBMS programme was ineffective. The overall impact showed that welfare loss to the society was 142.86 percent from the original condition. The biggest loss (two-third) was incurred by consumers and the remainder was incurred by producers.

### *9.2 Policy Implications*

Based on the findings of this study, the following policy implications and recommendations could be considered by the relevant authorities in order to improve the welfare of fishermen and consumers, as well as to maintain resource sustainability in Pemalang Regency.

#### 9.2.1 Fisheries resource management

The availability of relevant information is one of the basic requirements needed for effective fisheries management. At present, however, biological, technical, economic or even social information on the fisheries sector is very limited in Pemalang. Therefore, upgrading of the information or statistics related to resource management is very urgently needed for Pemalang fisheries. Beside improving the fisheries database, more effective enforcement in monitoring, control, and surveillance of resource utilisation are also needed, particularly when the resource is near or at the threshold condition like those in Pemalang.

#### 9.2.2 Implementation of the IBMS

Most fishermen in the study area lacked alternative employment opportunities in non-fishing sectors. At the same time, the IBMS so far was not successfuly implemented in Pemalang Regency due to the fact that the nearshore resource was overfished. Moreover, the schemes were distributed with the same instrument package to the target group. It is therefore recommended that the government or private creditors to diversify the schemes by providing different packages of engines, gears or type of boats to the recipients. Also, the creditors should extend this type of schemes to the large scale operators for deep sea fisheries which is still underutilized. This effort will not only encourage the commercialisation of the fisheries sector but also helps ease off the pressure on the nearshore fisheries resources in this region.

#### 9.2.3 Extension and training

The provision of extension/ training to upgrade the potential human development of fishermen on skill, mentality and psychology aimed at reducing their dependency on the fishery sector should be accelerated. Furthermore, this activity is

addressed to provide the alternative income sources or employment opportunities to fishermen. Similar recommendations for improving fishermen livelihood were also outlined by previous studies (Panayotou, 1985 ; Smith, 1979 and 1981 ; and Budiono, 1974).

### 9.2.4 Enhancement of fish marketing/ distribution and post harvest handling of fish

These are also recommended to improve the consumers and fishermen welfare. Not only will fishermen get better price for their products but also to provide consumers a better quality of fish with a reasonable price.

**CODE NAMES AND DEFINITIONS OF THE STANDARDIZED VARIABLES USED IN THE MODELS.**

| Code Names | Definitions |
|---|---|
| Endogeous: | |
| LTIQS | Quantity of fish supplied in the open market at period t (in an index) |
| LTIQD | Quantity of fish demanded in the open market at period t (in an index) |
| LTPFI | Aggregated price of fish at period t (in an index) |
| Exogenous/ Predetermined: | |
| LTIFE | Fishing effort, which was proxied from the number of trips of fishing boat at period t (in an index) |
| LCP1 | Probability to catch fish, which was estimated from the frequency distribution of catch at period t (in percentage) |
| $LTIQS_1$ | Lagged quantity of fish supplied in the open market at period t-1 (in an index) |
| $LTIQD_1$ | Lagged quantity of fish demanded in the open market at period t-1 (in an index) |
| LTIPS | Aggregated price of others commodities, namely, meats ( buffalo and mutton ); chicken (hybrid and local); eggs (duck and chicken);and tahu and tempe at period t (in an index) |

**TABLE 1**
**(CONTINUED).**

| Code Names | Definitions |
|---|---|
| LTIY | Income factor, which was proxied from corresponding Gross Regional Domestic Products (GRDP) at period t (in an index) |

Note:
All variables are in the form of log-linear and expressed as an index except for LCP1 which is in terms of percentage. The aggregation method used in analysis is the Geometric Index (GI). In some extent, to compute price aggregation, the GI can be written as follows:

$$P_{i(GI)} = P_{i1}^{ri1} \cdot P_{i2}^{ri2} \ldots\ldots P_{in}^{rin}$$

where : $P_{i(GI)}$ : the price index at period i
$P_{i1}$ : price of good 1 at period i
1,2,..n: kind of goods
ri1 : share (%) of respective price of each good to its total, at period i

# The Establishment of Chinese Marine Fisheries Laws and their Management Practice

**Guanghua Zhang**

Chinese Academy of Fisheries Sciences, Institute of Fisheries Economics Research,
N150 Quingta Cun, Yongding Road, Beiging 100039 China (PRC)

ABSTRACT

*The chinese goverment has always attached great importance to the establishment and development of marine fisheries laws, in 1986, the state promulgated "FISHERIES LAW", the first law about fisheries ever since the foundation of the People's Republic of China. On the basis of "FISHERIES LAW", a marine fisheries legislation system was formed with six titles : fisheries resources protection and conservation, fisheries management, fishing port superintendence, fishing boat inspection, fisheries telecommunication management and fisheries environment surveillance and protection.*

*Chinese marine fisheries regulations implement the guiding thought of "managing and thriving fisheries with laws", pay attention to advanced experiences of fisheries management in the world and stress the importance of adopting control measures in fisheries management. Between 1955 and 1980, the state stipulated the lines of closed areas for the bottom trawl of marine motor driven fishing boats in the Buohai Sea, the Yellow Sea, the East China Sea and South China Sea, and during the period, the limits for 600 HP fishing boats were also established. Between the years 1979 and 1989, new "REGULATIONS REGARDING FISHERIES RESOURCES PROPAGATION AND PROTECTION" and "TENTATIVE MANAGEMENT MEASURES ON THE ISSUES OF FISHING LICENCES" were issued one after another, and thus the fundamental principles for the protection and development of chinese marine fisheries resources and a system of fishing licensing were established. Thereafter, juvenile fish protection zones and closed fishing areas for the commercially important fish species such as prawn, cutlass fish and big yellow croaker were set up respectively in the Yellow Sea and the East China Sea, and the fisheries resources protection and conservation zones of Xisha and Znongsha were established in the South China Sea. The number of off-shore motor-sdriven fishing boats started to be controled in the 1987. The Buohai Sea has become a region with no trawl nets operation for the whole year round since 1988.*

## 1. THE MAIN CONTENT AND CHARACTERISTIC OF THE CHINESE MARINE FISHERIES LAWS

The Chinese government has always attached a great importance to the establishment and development of marine fisheries laws. In 1986, the state promulgated "FISHERIES LAW", the first law about fisheries since the foundation of

the People's Republic of China. On the basis of "FISHERIES LAW", a marine fisheries legislation system is formed with a content in six respects containing fisheries resources protection and conservation, fisheries management, fishing port superintendence, fishing boat inspection, fisheries telecommunication management and fisheries environment surveillance and protection.

The Chinese government exercises a unified leadership over fisheries management and superintendence and management by levels. In the proceeding of fisheries legislation, the fisheries authority of the state or at the central government level usually decrees significant fisheries legislation as basic law, according to which local governments have formulated specific regulations appropriate for the local conditions. Ever since 1979, various fisheries legislation and legislative documents issued by central government, provincial, regional and county levels approximate over 500 papers, the majority of which are devoted to the context of marine fisheries.

Chinese marine fisheries regulations implement the guiding thought of "managing and thriving fisheries with laws", pay attention to absorb advanced experiences of fisheries management in the world and stress the importance on the adoption of control means on fisheries management. In 1955 and 1980, the state set up the lines of closed areas for the bottom trawl of marine motor-driven fishing boats in the Buohai Sea, the Yellow Sea, the East China Sea and South China Sea, and during the period, the limits for 600 HP fishing boats were also established. In the year 1979 and 1989, new "REGULATIONS REGARDING FISHERIES RESOURCES PROPAGATION AND PROTECTION" and "TENTATIVE MANAGEMENT MEASURES ON THE ISSUES OF FISHING LICENCES" were issued one after another, and thus, the fundamental principles of the protection and development of Chinese marine fisheries resources and a system of fishing licensing were established. Thereafter, juvenile fish protection zones and closed fishing areas for the commercially important fish species such as prawn, cutlass fish and big yellow croaker were set up respectively in the Yellow Sea and the East China Sea, and the fisheries resources protection and conservation zones of Xisha and Znongsha were established in the South China Sea. The number of off-shore motor-driven fishing boats started to be controlled in 1987. The Buo sea has become a region with no trawl nets operation on the whole year round since 1988. The state adopted the principle of strict control and severe punishment in the practice of fisheries law, in line with the pertinent provisions of "FISHERIES LAW" ; the highest fine violation of the fisheries regulations amounts to RMB 50000 yuan and the heaviest penalty is to be put into custody for two years. On the other hand, the Chinese marine fisheries regulations pay great attention to guide and support the healthy development of marine fisheries production pursuant to national conditions. For instance, "FISHERIES LAW" has stipulated that the state shall support the development of off-sea and deep-sea fisheries in terms of capital, materials, technology, tax revenue etc, and the administrative department of fisheries management may levy on the fishing beneficiaries protection fee for fisheries resources enhancement which are devoted to the enhancement, the protection and conservation of fisheries resources. In the recent ten years, the amount of catch has increased to reach 600 000 tons minimum in China regarding off-sea fisheries, deep-sea fisheries and marine enhancement with prominent results.

## 2. FISHERIES LEGISLATION AND ITS MANAGEMENT PRACTICE IN THE EAST CHINA SEA REGION

The East China Sea region still has the highest level catch among the four marine regions in China ; it is also a region, with the participation of Japan and Korea (including South Korea), for fishing operations. Therefore, this region has always been deemed the key marine for the Chinese fisheries management.

In the East China Sea region, China has two fisheries management system : one of them is the central governmental fisheries management system and the other is a local one. They are relatively independent, but interrelated. The composition of the central governmental fisheries management system is shown on the figure attached. The Fisheries Management Bureau of the East China Sea region, a subordinate institution of the Ministry of Agriculture of the People's Republic of China, is located in the municipality of Shanghai. Directly under the Bureau, two fisheries management stations were set up respectively in two key fishing areas of the East China Sea. The major function of the institution is to exercice, on behalf of the state, the right of fisheries management and supervision of both internal and external matters in the East China Sea region and enforce the guidance and coordination in the provincial and municipal activities of fisheries management in the East China Sea region : under the principle of management by various levels, the scope of the jurisdiction covers all the water areas in the East China Sea region outside the limits of closed fishing areas for motor-driven fishing boats with bottom trawl nets. The local fisheries management institutions in the East China Sea

region are attached to the administrative authority of fisheries management in the governments at three levels such as provinces, municipalities (Shangai, Zhejiang province, Jiangsu province and Fujian province), regions and counties ; and their major responsibility lies in the activities of fisheries management and supervision within their administrative jurisdiction, which covers all the water areas within the limits of closed fishing areas for motor-driven fishing boats with bottom trawl nets.

Fisheries legislation in the East China Sea region deals mainly with two key points, one of them is to strengthen the protection and conservation of commercially important fish species ressources, the other one is to control fishing production. Seven major measures are as follows :

i) Setting up limits of closed fishing areas for motor-driven bottom trawler ; its width from the basic line of the territorial sea is about 12 sea miles. Setting the water areas within the limits of closed fishing areas for the operation areas of fixed nets, where motor-driven bottom trawlers are forbidden to enter operation all the year round.

ii) Enforcing closed fishing management to mass fishing trawlers. Four months, from July to October every year, are fixed for the closed fishing season.

iii) Formulating juvenile catchable standard for major commercially important fish species and maxima juvenile ratio allowed for the catch.

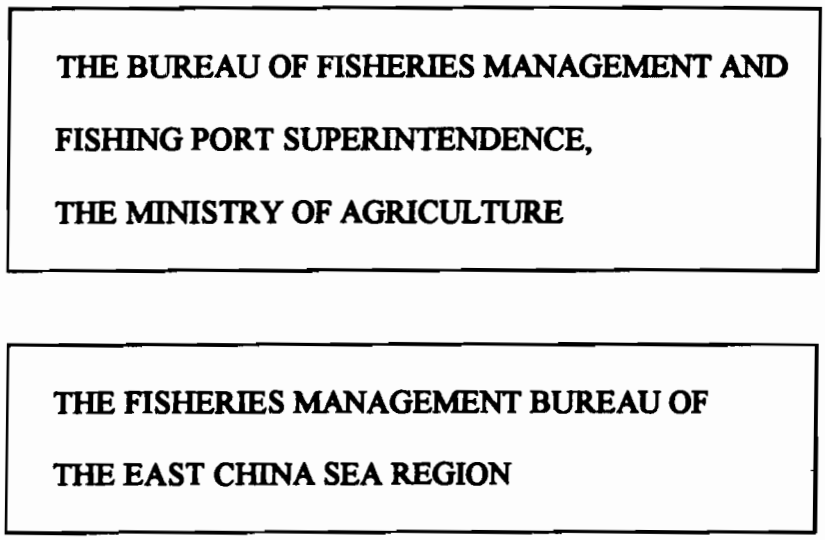
iv) In line with the fishing agreement between China and Japan, 6 juvenile fish protection and conservation zones and seven-season-closed fishing areas are set outside the limits line of closed fishing areas.

v) Distinction has been drawn to separate fishing grounds between offshore and offsea, to keep the fishing boat designated for offsea operations from entering into the fishing ground in the offshore.

vi) Identify and determine controlling horse-power criteria to limit the amount of motor-fishing boats allowed for operations in the offshore.

vii) Arranging the production on several major fishing grounds and fishing seasons in a unified manner. Stipulating the operation period and method of fishing operation and the total number of fishing boats in operation.

The fishing management in the East China Sea region has taken up the measures of direct management. On the land, the fishing licences of all kinds are verified and issued by fisheries management institutions and, at the sea, the violations of fishing regulations and laws of fishing boats and their productions are supervised, checked and dealt with by fisheries management boats to keep production order at sea. Apart from routine supervisory management, an on the spot chek-up is sometimes made by both central and local governments, at sea and on land. In the early 1980s, the management was mainly focused on the mesh size of fishing gear, the juvenile ratio in the catch and the closed fishing time for trawl nets of mass fisheries. In the late 1980s, the focus of the management turned to season-closed fishing grounds and protection and conservation zones for major commercially important fish species. With the efforts made over the decade, the velocity of deterioration of the major fisheries resources in the East China Sea has been eased off to some extent and the catch of big yellow croaker and small yellow croaker are beginning to come up again : the cutlass fish resources remain relatively stable. The resources of some species in some areas are rising prominently.



## 3. BILATERAL MARINE FISHERIES AGREEMENTS

In the past, the Chinese government has entered into the bilateral fisheries agreements on the development and utilization of marine fisheries resources with Japan, Korea and Vietnam, but has not yet established a regional marine fisheries agreement exceeding three countries.

In 1956, four countries like China, The Soviet Union, Korea and Vietnam signed an agreement on scientific cooperation and research which included marine fisheries but not productive utilization of fisheries resources. In 1957, China and Vietnam signed a fishery cooperation agreement on the issues of utilization of resources in the Beibu Gulf of the South China Sea (The Gulf of Tong King). In 1960, a similar agreement was also signed between China and Korea in the Yellow Sea. Once again in 1972, China and Korea have signed a fisheries mutual aid and cooperation agreement with further details. However, the agreements mentioned above were terminated at the expiration and were not renewed.

Today, Japan is the only country which enjoys bilateral fisheries agreements with China. The Sino-Japanese people-to-people fisheries agreement was signed in 1955 (it was changed to an intergovernmental agreement in 1975) and has been adjusted many times later pursuant to the changes of fisheries resources. The present executive fisheries agreement is the one adjusted in 1985. It has set up six protection and conservation zones and seven season-closed fishing areas outside the limit lines of closed fishing areas in the Yellow Sea and the East China Sea. Within the protection and conservation zones, the number of Chinese motor-driven fishing trawlers are limited to 624 boats and the number of Chinese purse seiner are limited to 70 groups. The number of Japanese fishing trawlers are limited to 444 ships and the number of Japanese purse seiner are limited to 25 groups. The average of annual fishing time for each protection and conservation zone is less than two months while in the year 1955, it had reached four months.

# Évaluation de l'Impact de la Flotte des Pays de la CEE dans l'Économie du Sénégal

**Moustapha Kébé**

Centre de Recherches Océanographiques de Dakar-Thiaroye (CRODT/ISRA) BP 2241 Dakar, Sénégal

RÉSUMÉ

*L'extension à 200 miles de la juridiction nationale offre à la plupart des pays côtiers de nouvelles possibilités de développer leurs pêcheries et de nouvelles responsabilités ; chaque pays étant libre d'exploiter les ressources vivantes au large de ses côtes au mieux de ses capacités et de l'intérêt national. Ainsi, les pays côtiers qui ne sont pas en mesure d'exploiter toutes ou certaines de leurs ressources cherchent à tirer le maximum de rente économique en signant des accords de pêche avec d'autres pays. C'est également le cas des pays ayant eu quelques expériences nationales malheureuses d'industrialisation de leurs pêcheries.*

*L'objectif de ce papier est de contribuer à la mesure et à l'analyse des bénéfices économiques que les pays côtiers africains tirent de l'exploitation de leurs Zones Economiques Exclusives par la flottille étrangère.*

*Depuis 1979, le Sénégal signe tous les deux ans des accords de pêche avec la CEE qui contiennent trois éléments principaux : l'accès des navires membres à la ZEE sénégalaise, à l'intérieur de certaines limites, une compensation financière versée directement par la Communauté et des redevances calculées sur la base des captures.*

*Il existe différents critères d'évaluation économique de l'impact de cette flotte CEE. Mais la complexité des filières thonière et chalutière de même que la nature des informations disponibles nous obligent à adopter une démarche analytique. Une typologie des agents économiques concernés par l'activité de la flotte CEE au Sénégal a été établie : les unités de pêche, les intermédiaires portuaires, les ateliers et chantiers maritimes, les entreprises de transformation, l'Etat et le secteur tertiaire.*

*Pour chacune de ces catégories ainsi définies, une évaluation économique a été faite. En fonction des informations disponibles, l'accent est mis d'une part sur la contribution au PIB, au PNB, l'influence sur la balance commerciale, et d'autre part sur les coûts (administration, subventions d'exploitation et d'exportation, infrastructures et effets externes).*

## 1. INTRODUCTION

L'extension à 200 milles de la juridiction nationale offre à la plupart des pays côtiers de nouvelles possibilités de développer leurs pêcheries et de nouvelles responsabilités ; chaque pays étant libre d'exploiter les ressources vivantes au large de ses côtes au mieux de ses capacités et de l'intérêt national.

Beaucoup de pays africains côtiers ne disposent pas des capitaux très importants qu'exige le développement d'une pêche industrielle rentable. Ceux qui ne sont pas en mesure d'exploiter toutes ou certaines de leurs ressources halieutiques cherchent à tirer le maximum de bénéfices en autorisant l'accès de leur Zone Economique Exclusive à des flottes étrangères. C'est le cas également des pays ayant eu quelques expériences nationales malheureuses d'industrialisation de leurs pêcheries.

C'est ainsi que les pays africains ont adopté une politique de concession de licences, liée également à des traditions de voisinage.

La conclusion d'un accord de pêche durant la période considérée, peut donner lieu à une série de contreparties économiques, commerciales et techniques, en sus des redevances perçues. Ces redevances qui peuvent revêtir plusieurs formes contribuent à améliorer la situation des Finances publiques des Etats côtiers par une entrée de capitaux.

En plus des marins nationaux à bord des bateaux, l'obligation faite aux flottes étrangères à débarquer tout ou partie de leurs captures contribue à l'approvisionnement des infrastructures locales de transformation et, dans une moindre mesure des populations locales. Par ailleurs, elle permet de créer une valeur ajoutée locale et de stimuler l'emploi.

Les pays signataires peuvent dans certains cas accorder aux pays côtiers des conditions tarifaires préférentielles permettant à ces derniers d'écouler aisément leurs produits.

Les accords de pêche peuvent venir en appoint à la recherche scientifique lorsqu'ils contiennent des dispositions visant à une formation des cadres nationaux chargés de la gestion du secteur des pêches et au transfert de technologie.

D'autres clauses sont stipulées dans les accords de pêche. Les pays signataires peuvent octroyer aux Etats côtiers des prêts à des conditions douces ou des capitaux non remboursables destinés à financer des projets de développement dans le secteur de la pêche. Des contreparties en nature peuvent être octroyées aux Etats riverains comme la construction de quais, de ports de pêche, etc...

Les accords de pêche signés par le Sénégal depuis son accession à l'indépendance peuvent être regroupés en trois grandes catégories (tabl. 1) :

(i) accords de réciprocité avec les pays voisins (Gambie, Guinée Bissau, Cap-Vert et Mauritanie) en raison des stocks partagés, de la migration des espèces et des pêcheurs. Le principe de l'accès réciproque aux ressources halieutiques présentes dans les eaux sous-juridiction des deux pays est souvent de règle ;

(ii) conventions sans protocole avec l'ex URSS et le Nigéria ;

(iii) accords de contrepartie de première génération (France, Espagne, Pologne et Italie) et de deuxième génération (CEE depuis 1979 et Japon en 1991). L'intérêt et les motivations de ces accords se justifient, en sus de compensations financières, par des avantages commerciaux, techniques et scientifiques. Ces accords concernent également des Etats côtiers africains comme la Côte d'Ivoire dont les ressources maritimes sont insuffisantes pour faire face à la demande locale de poissons.

En général chaque accord de pêche signé avec la CEE a une durée de deux ans et comprend trois éléments principaux : l'accès des bateaux européens à la ZEE sénégalaise à l'intérieur de certaines limites, une composante financière versée directement par la Communauté (paiement d'un montant forfaitaire au Trésor Public) et une redevance armatoriale en fonction du TJB (cas des chalutiers) ou des captures (cas des thoniers).

L'objectif de ce papier est de déterminer la contribution de ces accords de pêche avec la CEE au développement économique et social du Sénégal ; il s'agit de mesurer et d'analyser les bénéfices économiques que le Sénégal tire de l'exploitation de sa ZEE par la flottille CEE ainsi que les dépenses effectuées par l'Etat.

Dans un premier temps seront présentées et discutées les différentes méthodes d'évaluation généralement préconisées, puis seront analysés les effets économiques directs au niveau de chaque agent ainsi que les coûts afférents.

## 2. ASPECTS MÉTHODOLOGIQUES

### *2.1 Méthodes d'évaluation*

Parmi les méthodes d'évaluation généralement préconisées, l'approche économique apparaît comme la seule adaptée pour étudier le rôle des flottes étrangères dans le développement économique des Etats africains côtiers. En effet elle offre un cadre d'analyse utile dans la planification du développement des pêches.

La *méthode des effets* consiste essentiellement à rechercher les perturbations entraînées par le projet sur l'économie nationale. L'analyse de flux centrée sur la valeur ajoutée permet de connaître l'ensemble des effets du projet sur les différents agents économiques concernés. La détermination des multiplicateurs d'impact (revenu, emploi par exemple) exige des informations très fines sur la structure économique, en particulier si on utilise les tableaux entrées/sorties.

L'*analyse coûts/avantages* (méthode des prix de référence) fait apparaître les contextes du projet. Elle s'efforce de dire si les avantages (ce que la société obtient d'un projet) sont supérieurs à leurs coûts (sacrifices consentis pour produire ces avantages). Plusieurs ratios sont calculés : coûts/bénéfices, bénéfices nets actualisés, taux de rendement, etc...

L'*approche multi-critères* est basée sur le principe que les décisions ne sont pas prises sur un seul critère ; il faut rendre explicites les critères et les pondérer en fonction des préférences des décideurs. Il n'est pas facile d'établir les critères et la méthode exige de travailler en étroite collaboration avec les décideurs.

Aucune de ces méthodes d'évaluation économique recensées n'est spécifique à la pêche. Toute analyse économique dans ce domaine doit se faire à deux niveaux dans le processus de planification : la détermination du potentiel de capture et de l'effort de pêche, le calcul de l'effet sur l'économie nationale.

Seules les méthodes des effets et les modèles bio-économiques s'intéressent à la pêche. Elles ont fait l'objet d'une utilisation importante dans l'étude des pêcheries de la région COPACE et des Seychelles (Charneau, 1988 ; Francis et Christy, 1979 ; Gladicelli, 1988 ; Greboval, 1988 ; Horemans, 1988 ; Parker, 1986 ; Robinson, 1988 et Sok et *al*, 1987). En réalité les modèles bio-économiques ne constituent pas une méthode d'évaluation des effets de la pêche industrielle sur l'économie nationale. L'accent est mis essentiellement sur la détermination de la rente qu'on peut extraire de la pêcherie. La méthode exige un effort important de collecte de données biologiques et économiques.

### *2.2 Démarche adoptée*

La structure du capital détenu en partie par des intérêts étrangers ainsi que de la diversité des conditions d'emploi dans les différentes entreprises de pêche, rendent difficile l'appréhension rapide et correcte de l'impact de la flotte étrangère pour le Sénégal.

La nature des informations disponibles et la complexité des filières industrielles (thonière et chalutière) justifient la démarche analytique adoptée. Une typologie des agents économiques concernés par l'activité de la flotte étrangère (d'amont en aval) a été établie :

- les unités de pêche,
- les intermédiaires portuaires,
- les ateliers et chantiers maritimes,
- les sociétés de transformation du poisson,
- l'Etat et les établissements publics.

Pour chacune des quatre premières catégories ainsi définies, une évaluation économique a été faite pour l'année 1987 (Kébé, 1989) ; les données ne sont pas disponibles pour les sociétés de transformation du poisson. L'impact économique de la flottille CEE qui a exploité les eaux sous juridiction sénégalaise pendant l'année de référence a été déterminé en évaluant les bénéfices et les coûts liés à l'activité de cette flotte.

Au préalable il nous semble nécessaire de préciser la notion de résidence en vue de mieux cerner le statut juridique des unités de pêche.

Tout agent national ou étranger ayant un centre d'intérêt économique durable sur le territoire, c'est-à-dire y effectuant des opérations pendant un an au moins est considéré comme agent économique résident. En appliquant cette définition aux flottilles, on se rend compte qu'il y a équivalence entre les notions de flottille résidente et de flotte basée ; un bateau basé étant un bateau appartenant à un agent (ou une société) national ou un bateau battant pavillon étranger, mais ayant Dakar comme port d'attache.

Dans ce travail, nous prenons en considération les bateaux CEE aussi bien au niveau de la flottille résidente que de la flotte non basée.

La flottille CEE basée est constituée de thoniers canneurs français et espagnols, de chalutiers français et italiens, travaillant exclusivement à partir du port de Dakar.

Les produits d'exploitation de ces bateaux ainsi que les charges afférentes sont l'objet de transactions entre (ou avec) des agents économiques nationaux. Il faut signaler cependant que, même s'ils sont obligés de débarquer à Dakar pour approvisionner les usines, les bateaux étrangers qui sont immatriculés au quartier des Affaires Maritimes d'origine rentrent dans leurs pays respectifs pour les travaux de gros entretien.

La flottille CEE non basée est composée de thoniers senneurs français et espagnols, de chalutiers italiens, grecs et espagnols qui relâchent occasionnellement dans le port de Dakar. Ils effectuent des escales commerciales (débarquements et/ou transbordements sur un cargo) ou des escales techniques (relève d'équipage en rade extérieure, entretien, réparation, avitaillement...). Leur présence génère des flux physiques ou monétaires. Les dépenses effectuées sur le territoire sénégalais concernent l'avitaillement (carburant, sel pour saumure, vivres pour l'équipage, glace, éventuellement pièces détachées), les petites réparations ainsi que les droits d'utilisation des services portuaires. Les consommations intermédiaires des bateaux étrangers en escale à Dakar constituent des produits d'exploitation des sociétés d'avitaillement et sont autant de demandes indirectes auprès des producteurs locaux.

## 3. EFFETS ECONOMIQUES DIRECTS

### *3.1 Dépenses de la flotte CEE non basée*

Les dépenses totales d'avitaillement de la flotte étrangère ont été estimées en 1987 à près de 481 millions de FCFA dont 39 % pour les chalutiers congélateurs, 32 % pour les thoniers senneurs et 29 % pour les chalutiers glaciers (Kébé, 1989).

Le poste carburant en admission temporaire n'a pas été pris en compte. En effet, depuis le début de l'année 1987, on assiste à un déroutement des navires étrangers et sénégalais à Las Palmas pour souter, en raison de l'enchérissement du pétrole brut importé par la Société Africaine de Raffinage (SAR). Il faut également préciser que les retombées de l'activité thonière sur l'exploitation du gisement de sel de Retba sont sans doute plus grandes encore car une partie de l'approvisionnement en sel des senneurs français et espagnols dans le sud du Golfe de Guinée est assuré par des cargos venant de Dakar (Charneau, 1988). Par ailleurs les autres dépenses effectuées par les senneurs étrangers (gaz, entretien et petites réparations), considérées comme d'importance plus faible, n'ont pas fait l'objet d'une évaluation.

### *3.2 Approvisionnement des usines locales*

Pour la flotte CEE basée à Dakar, les débarquements ont atteint 9 968 tonnes en 1987 : canneurs français 8 028 t, canneurs espagnols 936 t, chalutiers français et italiens 944 t (Kébé, 1989).

Les débarquements et transbordements de la flotte non basée ont été de 27 527 tonnes : thoniers 19 152 t, merlutiers espagnols 667 t, crevettiers espagnols 1033 t, chalutiers italiens et grecs 6 675 t (Kébé, 1989). Les crevettiers sont très souvent contraints à débarquer leurs captures aux îles Canaries pour des raisons commerciales.

Au total la pêche étrangère a contribué en 1987 à l'approvisionnement des usines de Dakar en matière première pour un volume global de 35 795 tonnes dont près de 72 % par les bateaux non basés.

### *3.3 Rémunération des équipages sénégalais*

En 1987, on a recensé 1482 marins sénégalais embarqués à bord des unités étrangères, à des postes d'hommes d'équipage exclusivement. La masse salariale correspondante injectée dans l'économie sénégalaise est estimée à 1,5 milliard de FCFA.

*3.4 Intermédiation portuaire*

La pêche industrielle génère des activités spécifiques avant même la prise en charge du produit par les usines de transformation. Il s'agit de la manutention réalisée en grande partie par les dockers, des fonctions liées au trafic international (consignation et transit) ainsi que de l'aconage.

La plupart de ces fonctions sont assurées par des entreprises intégrées privées sénégalaises. Dans le domaine de la consignation, une concurrence assez forte s'est manifestée depuis quelques années ; certains armements ont créé leurs propres structures à Dakar.

Les dockers qui effectuent la manutention portuaire sont soit des professionnels, soit des occasionnels, soit recrutés ponctuellement sur simple présentation de la carte d'identité.

Les résultats des investigations menées montrent que la manutention du poisson débarqué par la flotte étrangère représente en moyenne 10 % de l'activité du port soit environ 39 000 heures de travail docker et 8 000 heures de travail pointeur. La masse salariale engagée est d'environ 160 millions de FCFA, ce qui correspond à un taux de salaire moyen horaire de 402 FCFA (dockers et pointeurs confondus). Cette évaluation ne tient pas compte de la manutention informelle qui paraît importante ; ce sont soit les équipages qui débarquent eux mêmes souvent le produit, soit des entreprises non agréées qui s'en chargent.

*3.5 Entretien et réparation navale*

Pour la flottille de pêche étrangère, l'activité des chantiers et ateliers maritimes se limite à l'entretien et à la réparation. Le marché est partagé pour l'essentiel entre l'atelier d'entretien des canneurs géré par la coopérative basque Lagun Artean et la société Dakar Marine.

Le niveau d'activités de l'atelier coopératif s'est considérablement réduit au cours de ces dernières années en raison de la baisse sensible du nombre d'adhérents. Actuellement le personnel est limité à 2 personnes.

La société Dakar Marine peut prendre en charge les réparations des senneurs et chalutiers étrangers. L'intéressement au projet de grands chantiers belges et français a permis le financement d'investissements lourds qui font de cet atelier l'un des mieux équipés de la région ouest-africaine. Cependant les tarifs et les niveaux de prestations rendues limitent fortement sa fréquentation par la flotte de pêche étrangère qui lui préfère les chantiers des îles du Cap Vert, d'Espagne (îles Canaries) et de France (Charneau, 1988).

Pour l'année 1987, le montant facturé des interventions de Dakar Marine représentait 42 % du chiffre d'affaires global, soit 1,34 milliards de FCFA dont 72 % pour les bateaux basés (41 %) et non basés (31 %) autorisés à pêcher dans les eaux sous juridiction sénégalaise, et 28 % pour les navires de pêche russes qui n'opèrent pas officiellement dans la ZEE sénégalaise (Kébé, 1989).

*3.6 Recettes publiques*

L'activité des agents économiques dans la pêche fait l'objet d'une fiscalisation de la part des pouvoirs publics. Ces flux sont complétés par la rente économique extraite des partenaires étrangers venant pêcher dans les eaux sous juridiction sénégalaise.

**3.6.1 Recettes fiscales**

Elles se présentent sous quatre (4) formes distinctes :

(i) l'imposition sur le revenu des personnes physiques : la part de la masse salariale revenant à l'Etat sous la forme de l'impôt sur le revenu (IGR), de l'impôt sur les traitements et salaires (ITS) et de la taxe représentative du minimum fiscal (TRIMF). Les marins sénégalais embarqués à bord des bateaux étrangers versent à l'Etat 181,7 millions de FCFA, les dockers et pointeurs 19,2 millions de FCFA ;

(ii) l'imposition sur les bénéfices industriels et commerciaux : le taux est de 33 % mais les entreprises de pêche échappent en grande partie à l'impôt, tant les bénéfices déclarés sont faibles ;

(iii) la taxation sur les biens et services : les données ne sont pas disponibles pour évaluer d'une part les taxes perçues par l'Etat sur la production et les intrants importés, et d'autre part la part à imputer à la flotte étrangère ;

(iv) la perception des droits et taxes de douane : l'Etat est déficitaire à ce niveau. En effet les usiniers ne paient pas de droits d'entrée pour les matières premières importées qui entrent dans la fabrication des conserves. Les consommations intermédiaires importées sont placées sous le régime de l'admission temporaire. La plupart des produits de la pêche exportés sont exonérés de droits de douane.

### 3.6.2 Recettes non fiscales

Elles sont constituées par les contreparties financières de l'accord de pêche ainsi que les recettes de la Caisse d'Encouragement à la Pêche et à ses Industries Annexes (CEPIA).

La compensation financière directe de la CEE est fixée pour l'accord qui couvre la période allant du 01/10/86 au 28/02/88 à 1,7 milliards de FCFA auxquels s'ajoutent 1,55 milliards au titre de l'augmentation des droits de pêche à partir du 1er mars 1987. Le Centre de Recherches océanographiques de Dakar-Thiaroye (CRODT) a reçu une enveloppe globale de 90 millions de FCFA au titre de l'aide à la recherche scientifique et technique. Dix bourses d'étude de 5 ans au plus chacune sont accordées au sein d'établissements de formation pour la CEE.

Pour 1987, le Sénégal a reçu des bateaux de la CEE la somme de 260,6 millions de FCFA correspondant aux droits de licence de pêche, soit 53 % du montant total perçu aux licences. Globalement il faut compter environ 1,6 milliards FCFA au titre des compensations et redevances contre 4,9 milliards FCFA en 1989.

### 3.6.3 Autres recettes publiques

Les autres recettes du compte spécial de la CEPIA sont constituées par 60 % du produit des amendes et infractions à la réglementation (les 30 % vont à la Marine Nationale et les 10 % à l'Administration des pêches (DOPM) ainsi que par les 2/3 des montants des taxes parafiscales (cotisations des exportateurs et professionnels de la pêche). Ces recettes intéressent l'ensemble de la flotte industrielle (nationale et étrangère).

### *3.7 Recettes du port autonome de Dakar (PAD)*

Les recettes enregistrées par le PAD en contrepartie des services fournis à la pêche sont de 4 types :

(i) les recettes sur les navires constituées par les redevances de pilotage, d'amarrage, de séjour et d'utilisation du plan d'eau ;

(ii) les recettes sur les marchandises c'est-à-dire les quantités physiques transbordées ou embarquées. Le thon transbordé bénéficie d'un coefficient réducteur destiné à favoriser le transit des flottes étrangères par le port de Dakar ;

(iii) les recettes domaniales correspondant au droit d'utilisation des terre-pleins, hangars et terrains ;

(iv) les autres recettes perçues pour la cession d'eau, d'électricité et de matériel.

Au cours de l'exercice 1986-1987, les recettes enregistrées par le PAD pour les services rendus à la flotte de pêche s'élevaient à 1,1 milliard de FCFA, soit 16 % des produits d'exploitation du PAD. S'y ajoutent les recettes domaniales hors pêche payées par les usines et frigorifiques traitant le poisson dans l'enceinte du port ainsi que les baux des usines et des différents intermédiaires situés hors enceinte mais sur le territoire du PAD. Ainsi plus de 1,4 milliard de FCFA ont être perçus de la pêche.

### *3.8 Cotisations sociales*

Les cotisations sociales sont versées aux caisses de sécurité sociale, de retraite et d'assurance maladie par les armements. Les charges sociales pour le personnel sénégalais représentent 45,4 milliards (forfait patronal de 3 % de la masse salariale). Les marins français, bien qu'affiliés au régime social français versent une cotisation à la caisse de sécurité sénégalaise de même qu'un forfait patronal de 5 % de la masse salariale.

## 4. ANALYSE DES COUTS INDIRECTS

On peut distinguer trois niveaux de coûts liés à l'activité de la flotte étrangère : coûts administratifs, coûts d'investissement et facteurs externes.

### *4.1 Coûts administratifs*

Ils sont liés à la négociation, la gestion et la surveillance des activités de pêche.

#### 4.1.1 "Subventions"

L'Etat alloue aux entreprises de pêche deux types de "subventions". La subvention d'exploitation concerne le carburant consommé par les bateaux (gazoil mer). Elle se décompose en une détaxe (manque à gagner constitué par la TVA SAR et la TVA sur le "prix économique stabilisé") et une intervention positive de la Caisse de Péréquation et de Stabilisation des prix. Le montant des subventions totales sur le gazoil mer consommé par la flottille étrangère a été estimé à 275,5 millions de FCFA.

Les produits de la mer bénéficient du régime général d'incitation à l'exportation au même titre que les produits transformés. Cette prime d'incitation est passée de 10 % de la valeur FOB à l'exportation du produit en 1980 à 15 % en 1983, puis à 25 % de la valeur ajoutée industrielle nationale (VAIN) incorporée dans le produit fini à partir de 1986. La VAIN est déterminée par application directe d'un coefficient technique à la valeur FOB à l'exportation du produit, soit 15 % pour les poissons, crustacés et mollusques frais, réfrigérés ou congelés, 15 % pour la farine de poisson et 30 % pour les préparations de poisson, de crustacés et de mollusques.

Par ailleurs certains produits halieutiques (crevettes et calmars) bénéficient du système de stabilisation des recettes d'exportation (STABEX) existant entre la CEE et les pays ACP liés par les accords de Lomé. Il existe également des conditions préférentielles pour les importations provenant des pays ACP telle l'absence de taxe douanière lorsque les produits répondent à un certain nombre de critères quant à l'origine et la salubrité.

#### 4.1.2 Autres coûts administratifs

La cotisation du Sénégal à l'ICCAT [1] est calculée chaque année en fonction des déclarations de prises de la flotte nationale et des quantités traitées par les conserveries. Elle est de l'ordre de 5 millions de FCFA.

Le budget alloué au projet Protection et Surveillance des Pêches au Sénégal (PSPS) était de 200 millions de FCFA pour l'exercice 1987-1988 dont 23,4 milliards comme masse salariale des 98 observateurs à bord des bateaux étrangers.

### *4.2 Coûts d'investissements*

Ces coûts concernent essentiellement les infrastructures et services à terre. Il n'est pas possible de définir la proportion de ces investissements qui sont directement et uniquement liés à la pêche étrangère CEE.

### *4.3 Facteurs externes*

Les coûts sociaux sont liés à la compétitivité entre les bateaux CEE et les pêcheurs sénégalais pour l'accès à la ressource et éventuellement aux marchés. Ces frais ne sont pas négligeables mais leur évaluation est difficile.

Il y a également les rejets en mer effectués par les chalutiers crevettiers. Ils constituent une perte de production sur les long et moyen termes. Le rapport poissons rejetés/poissons conservés est de 2,5 en saison chaude contre 1,6 en saison froide (Caveriviere et Andriamirado, 1988).

1. ICCAT : International Commission for Conservation of Atlantic Tuna

## 5. CONCLUSION : QUELLE STRATEGIE DE DEVELOPEMENT DES PECHES

Au total les entreprises de pêche CEE intéressent à divers titres l'économie sénégalaise. Le produit intérieur brut (PIB) n'est affecté que par les unités basées. La présence des marins sénégalais à bord des chalutiers et thoniers étrangers génère des paiements de facteurs qui interviennent en partie dans le produit national brut (PNB). Les retombées économiques de la flotte CEE sont loin d'être négligeables pour le Sénégal.

La politique de concession de licences, adoptée par la plupart des pays africains côtiers au lendemain des indépendances, était considérée comme une situation provisoire, un premier pas dans le processus de développement national. L'objectif à moyen terme était de constituer une flotte nationale capable d'exploiter de façon optimale leurs ressources halieutiques.

Mais force est de constater, 30 ans après, que les flottes étrangères continuent à pêcher dans leur ZEE et semblent donc réaliser des profits. Dès lors on peut se demander en toute logique si leur présence ne peut pas constituer en soi un frein au développement des capacités nationales.

Par ailleurs, malgré l'augmentation des bénéfices indirects que ces pays étaient en droit d'attendre de l'exploitation de leur ZEE par les flottes étrangères, cette stratégie de développement est marquée principalement par le manque de contrôle qu'ont ces pays sur les ressources halieutiques et les marchés de consommation finale de leurs produits.

La politique de développement mise en oeuvre dans le secteur de la pêche par un Etat côtier influence fortement les résultats économiques du secteur dans les Etats voisins. Il est nécessaire alors de mener une analyse régionale de l'impact de la flotte étrangère dans les pays africains côtiers qui partagent les mêmes stocks de poisson. Ceci aiderait à harmoniser les politiques en matière de négociation des accords de pêche, notamment avec la CEE.

La flotte industrielle sénégalaise est confrontée actuellement à d'énormes difficultés liées à sa vétusté et à une mauvaise gestion. En revanche la pêche artisanale a connu d'importants développements durant ces dernières années grâce à son dynamisme et à sa capacité d'adaptation aux changements. Son impact dans l'économie sénégalaise n'est plus à démontrer. Les emplois générés sont importants : 150 000 (soit 10 % de la population active nationale) dont 35 000 pêcheurs contre 10 000 pour l'industriel (Chaboud et Kébé, 1990). La valeur ajoutée dégagée par ce sous-secteur artisanal en 1987 est de 71,5 milliards de FCFA représentant 62 % de la valeur ajoutée induite totale du secteur des pêches au Sénégal (Brendel et *al*, 1992). Loin de reposer sur une économie de subsistance, la pêche artisanale contribue largement à l'approvisionnement des usines de la place (cette filière représente 20 % de la valeur ajoutée induite par le sous-secteur), et par là au rééquilibrage de la balance commerciale du pays.

Assurant plus des 2/3 des débarquements de poisson (250 000 tonnes en moyenne), elle couvre une part relativement importante des besoins en protéines animales des populations aussi bien rurales qu'urbaines.

Dans le souci de protéger ce sous-secteur dont le développement est considéré comme prioritaire et de permettre une gestion rationnelle des ressources halieutiques, l'Etat a pris un certain nombre de mesures pour mieux contrôler leur exploitation :

(i) instauration d'un Code de la pêche (Loi du 18 août 1987) qui arrête les droits d'usage et les normes d'utilisation des potentialités halieutiques nationales ;

(ii) élaboration d'un système de surveillance aérienne et maritime des eaux relevant de la juridiction du Sénégal, pour le respect des réglementations en vigueur ;

(iii) mesures d'allégement fiscal dans le cadre du Code des investissements (Loi 87-25 du 18 août 1987) : exonération des droits d'entrée des navires et des équipements de pêche, assouplissement de la législation sociale pour tenir compte du caractère saisonnier des activités, liberté de transfert des capitaux et revenus générés pour les armateurs.

# Bioeconomic Considerations regarding the Opening of a Autumn Fishery on Capelin in 1991

**Per Sandberg and Peter Gullestad**

Directorate of Fisheries, Box 185, 5002 Bergen, Norway

ABSTRACT

*North-East Artic Cod preys on Barents Sea Capelin. Knowledge about this multispecies effect is important when deciding when to fish Capelin.*

*This poster deals with relevant bioeconomic variables in such a decision process. In lack of formal bioeconomic models, bioeconomic reasoning was used when deciding whether or not to open a fishery on Capelin. Quantitative and qualitative arguments in this reasoning are briefly discussed.*

## 1. INTRODUCTION

North-East Arctic Cod preys on Barents Sea Capelin. Both species are of great commercial value in Norwegian fisheries, Capelin mainly for reduction purposes. Due to an abrupt change in the Barents Sea ecosystem combined with a too high fishing mortality, the Capelin stock was at a historically low level in 1986. As a consequence, the cod stock lost its main diet. In lack of Capelin, the growth rate for cod went down, cod behaved cannibalistic and the stock was severely reduced. A moratorium on the Capelin fishery was established.

A harsh economical climate began for Norwegian fishermen. Several meal factories were forced to close business. Five of these factories, situated in the north of Norway, were in the years of the moratorium given subsidies from the government to be able to function in an expected future Capelin fishery.

## 2. ACFM'S ADVICE ON A AUTUMN FISHERY OF CAPELIN AUTUMN 1991

Due to the moratorium imposed in 1986, the Capelin stock recovered to an exploitable level in 1991. With the consequences of overfishing in 1986 in fresh memory, one was anxious to know ACFM's recommendation on an autumn

fishery of Capelin in 1991. Relevant arguments for such a TAC would be the net benefits of a Capelin fishery versus the potential negative effects (costs) this fishery might have on the cod fishery. Besides, an autumn fishery should be no threat to the Capelin target spawning stock biomass, and should be regulated to avoid fishing mortality on immature Capelin.

Such considerations involves bioeconomic arguments. With its role as a biological advisor, ACFM did not give a clear recommendation about whether or not to open an autumn fishery on Capelin.

## 3. RELEVANT BIOECONOMIC VARIABLES

In lack of formal bioeconomic models, the Directorate of Fisheries had to rely on bioeconomic reasoning when advising the Minister of Fisheries about whether or not to open the fishery. In this analysis we focused on gross value, or prices. Harvesting costs were set to zero. The most important variables in the decision process were identified (see table 1).

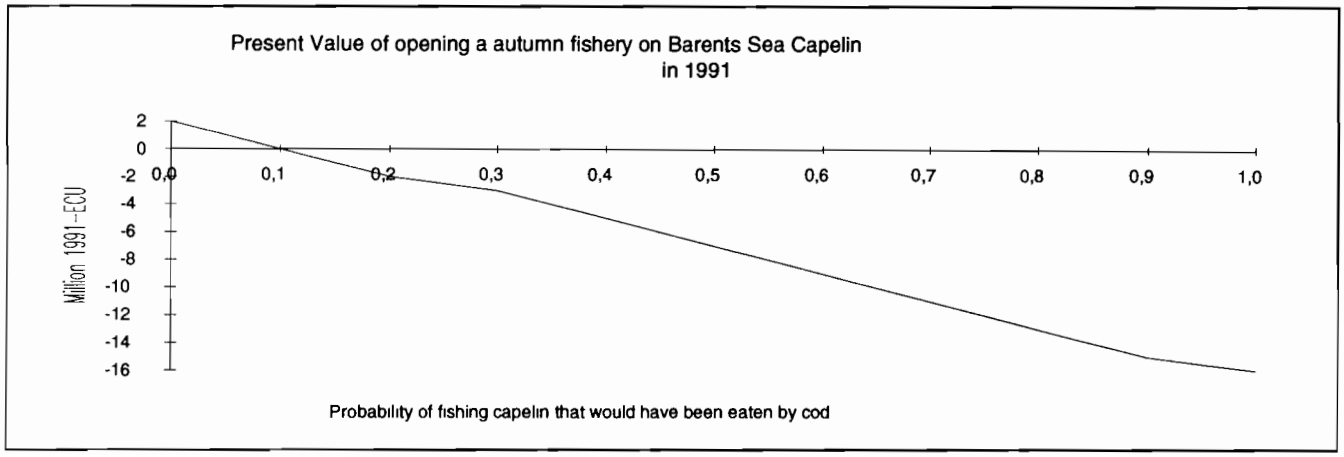
### *3.1 Quantitative analysis*

With the expected values shown in table 1, we calculated the present value (PV) of opening a autumn fishery on Capelin under a TAC of 300.000 tonnes (a quota allocation of about 180.000 tonnes to Norway). The figure 1 shows how the value of opening a autumn fishery depends on the probability of fishing Capelin that otherwise would have been eaten by cod.

After consulting the Institute of Marine Research (IMR) in Bergen, we found that with the prevailing stock sizes of cod and Capelin in the Barents Sea, the probability that a TAC on 300.000 tonnes should conflict with the cod's food demand was close to zero.

### *3.2 Qualitative analysis*

A autumn fishery on Capelin would strengthen the financial position of the fish-meal factories in the northern part of Norway by prolonging their annual operation time. The existence of these factories is a precondition for participation of a part of the fleet fishing Capelin in the winter (small vessels using trawl and purse seine). A autumn fishery on Capelin would therefore be a support to the continued participation of this fleet.



## 4. DECISION

Regarding both quantitative and qualitative factors, the Directorate of Fisheries recommended the Minister of Fisheries to negotiate with the USSR to open a fishery under a TAC at about 300.000 tonnes. Quantitative arguments did not favor strongly either position. This recommendation was therefore principally based on the qualitative arguments dealing with the need for the fish-meal factories' role for a continued participation of the small vessels in the Capelin fishery.

# "Sevryka" - A new Competitor in the European Seafood Market ?

**Frode Nilssen**

FORUT (Foundation for Applied Research at The University of Tromsø). P.o box 2806, 9001 Tromsø, Norway

ABSTRACT

*The paper gives an overview of the political/economical changes in the former Soviet Union, and on the basis of this makes a brief presentation of "ARP Sevryba's" competitive conditions. According to Porter (1990) a nation's competitiveness depends on the capacity of its industry to upgrade. During the last decade the former Soviet Union has been subject to extensive political changes and hence rather comprehensive changes in the enterprises national factor conditions. This fact is believed to have a significant impact to the economic performance of "ARP Sevryba" as a potential competitor on the European seafood market.*

## 1. INTRODUCTION

During the last years the former Soviet Union and Russia has gone through extensive political and structural changes in the hope to both improve her internal and external economic performance. One of the sectors affected by the reforms is the fishing industry. Although the former Soviet fishing industry is referred to as a strategic sector due to its importance as a food supplier to the domestic market, the industry also plays an important role as an exporter of seafood, and to a certain extent a valuable cash cow of foreign currency.

Taking this into account it is likely to believe that the changes has led to some adjustments of the strategy - or goals - of the Russian enterprises. One of the possible changes is that they will head towards a more aggressive performance in the international (European) market for cod-fish and shrimps, which are two major species in the northern fishing grounds, both related to volume and value. To examine this hypothesis we are looking into the Soviet seafood company of the northern areas, "ARP Sevryba" as a case study.

The main focus of the study is to analyse the organisation "Sevryba" and identify to what extent the changes in the national environment (attributes) have influenced on the export performance of the "Sevryba" association and its member

companies. Hence the study will place its main emphasis on the process of reorganisation of "Sevryba" and the implications thereof leading to potential changes in the producton and marketing of seafood i Russia and the Western Europe.

The aim of this paper is to present some prelimenary results from the ongoing study of the Northern Fishery Association "ARP Sevryba". This paper provides an overview of the economic reforms in the former USSR and the organisational development of "Sevryba" through the last decade. The paper will hopefully contribute to a better understanding of the organisation of the North-West Russian fishing industry both as a potential trade partner and as a competitor in the European seafood market. The results presented here are prelimenary and due to the early stage in the project the main export data will be related to the USSR export of seafood to Norway. It is beyond the scope of this first draft to analyse this problem within a theoretical framework. More detailed information and thorough analysis will be presented in the main report from the study and in later papers.

## 2. RESEARCH DESIGN AND DATA COLLECTION

The work with this study started during the late summer 1991. The "first round" in our data collection effort was carried out during the fall, prior to the dissolution of the Soviet Union. Hence both the terms Soviet Union and Russia are used throughout the text. In the study we are focusing on the organisational changes and the development of "Sevryba" as an industrial organisastion and a managerial instrument to the central administrative planning system. Through the many and in some respect radical changes during the last years the 1980-ies and the beginning of the 90es several new potential possibilities for the development of the Russian seafood industry have occurred. Studies of Eastern Europe and especially the former Soviet Union brings up several both methodological and practical problems which one normally do not face in similar studies in the western world. The most decisive amongst these factors are language barriers, time, validity and availability of information especially related to figures and statistics.

The main emphasis of this study is to provide insights into the North-West Russian fishing industry both as a potential trade partner and as a competitor in the European seafood market. The written material available about the russian seafood industry is scarce. Hence this study is conducted as an expolorative study with the goal both to gain insights and to be able to breaking our vague problem statements into a more precise form as in a specific hypotesis.

The empirical data in this paper are based on both primary and secondary data. The primary data obtained consists of unstructured interviews with 14 senior officers and other key personel in "Sevryba" and her member companies. As complementary datasources several journals, newspapers, official statistics and other available material are used.

Central national plans, like in Russia, are with few exceptions broken down to the enterprise level and the plans are carried out by the enterprises as obligatory plan directives. Nove (1986 p. 9) states the following distinction between the centrally planned economy and the more market driven economies :

> *".....The essential distinguishing feature is that the producing enterprise are **told** what to do, whereas in a different model (eg. Yugoslavia, Hungary) they have much greater power deciding what to produce through contractual relations with customers".*

As a theoretical basis for this study we have chosen the theories about organisational behaviour and industrial buying behaviour with special emphasis on Decisison System Analysis (DSA) (Møller 1985, Webster 1984, Wind and Thomas 1980, Sheth 1973). This approach provides, to the authors opinion, a more flexible theoretical fundament for the study. The outline of the theories will be presented in later papers as indicated in the introductory chapter.

## 3. CENTRALLY PLANNING AND ECONOMIC REFORMS

The socialistic (command-) economy was introduced in the Soviet Union after the period of New Economic Policy (NEP - lasting from 1921 to 1928). Even though there have been several reforms and formal changes during the period from

1928 and up til the beginning of the 1980-es[1], it can be fair to say that the basic idea and the execution of the Soviet economic system have not changed notably. The evolution of the central planning in the Eastern Europe have led to a different industry structure, industrial behaviour and management than we know from the industrial organisations in the western world. Critical factors as input, output, prices and wages, sales and purchases and so on was and are still (to a large extent) determined and planned by central political and planning authorities.

> *"...in this manner, planners preferences supplant consumer souveregnty by taking rescource allocation out of the hands of the consumer and placing it on the hands of the administrative apparatus* (Gregory and Stuart 1986 p. 9).

To complement and support the planning system there are an intricate system/apparatus for supervising and controlling the enterprises and their performance, particularly in respect to their fulfillment of the directed plans for production. Likewise the export activities has been correspondingly subject for the system of centralised decision making. As a consequence of the taut central planning and control the soviet enterprises have not paid very much attention to other companies and/or local buyers and potential customers or consumers (Freris 1984). On the other hand the planners and planning authorities have received substantional attention from the enterprise managers.

From the mid 1980ies the need for more far reaching economic reforms have been at the core of political discussions in the Soviet Union. These discussions and the following process ended up with a new law proposal regulating the soviet enterprise. The legislation was finished and implemented in the mid 1987 (The USSR law on State Enterprises).

The main objectives of the economic reforms for internal economic activity are to enlarge the independence of state enterprises and collective farms, and to extend the possibility of economic activity for other co-operative enterprises and individuals. In addition one sought to incourage co-operartion between the above mentioned soviet enterprises (ADECO 1989).

One of the driving forces for the perestroika has been the decision to provide selected Soviet industries and enterprises with direct access to foreign markets (United Nations 1988). Further the new economic mechanisms concerning foreign economic relations was in principle aiming towards a system for more decentralised foreign trade, and to link the enterprises performance more closely to wages and profits connected to their (foreign) trade activity. But even though the reform process for restructuring of the soviet economy was ment to lead to an increased local autonomy and decentralisation there still are many both legislative and practical barrieres for independent economic performance of the single enterprise. One of the interconnected problems tied to this fact is the presence and status of the planning apparatus and central bodies still striving for fullfilment of plans and regional needs/demands (Dyker 1992).

## 4. "SEVRYBA"

### *4.1 Introduction*

Like other soviet economic organisastions "Sevryba" have been submitted to central planning and control and represents a part of the total soviet economic system. In the total measure of the Soviet Union economy, foodstuffs and raw material for production of foodstuffs only represents 1.5 % of the total export value in 1988 (ITC 1989). In this respect Seafood does not represent a major sector in the soviet economy as an export commodity. However the fishing industry together with agriculture is considered as important to the former Soviet Union and have a relatively strong strategic significance. The main reason for this is tied to the all union goal to be self supplied with foodstuffs based on these two branches. As concerned to the fishing industry the national goal is to raise the per capita consumtion of seafood (to 19 kilograms a year by 1990). The strategic significance have been underscored several times by official spokesmen, and also in a report presented by the USSR ministry of foreign relations (Op cit p. 55) :

> *"The fishing industry has a prominent role to play in the implementation of the country's food programme".*

As related to "Sevryba", the Kola region which is the home base for "Sevryba", is the second largest supplier of seafood to the domestic Soviet market (Doiban et al 1992). According to the "Sevryba" association the total output represents

1. Especially in the late 50ies and early 60ies

20 % of the total seafood production of the USSR. The administration and the main fishing and processing facilities are located in Murmansk, the capital of the Kola region. Hence Murmansk is the site of the largest soviet fish processing combine (Murmansk Fish Processing Plant) and also the home base of the three largest fishing fleets (Murmansk Trawl Fleet, "Murmanrybprom" and "Sevrybcholodflot").

Even though the main base of "Sevryba" is situated in Murmansk the association also have several units in Arkhangelsk regions and in the Karelian republic[2]. The association which was founded in 1990 consists of 24 production units, fleets and other independent companies. The association employed by mid 1990 about 77.800 people, and was by that one of the largest regional fishing associations in the former USSR. "Sevryba" is a vertically integrated structure and consists of both catching, processing, subsidiary and research units. In addition there also is a "marketing" or sales unit called Sevrybsbyt. In 1990 the total catch was ca 1,6 million tons of which edible products amounted ca 900.000 metric tons. The export represented about 10 % (120-140.000 metric tons) of the total catches. The most important fish catches (in volume) are pelagic fish like macrel, sardines, herring and anchovy. Other important species are whiting, cod fish and some shellfish. These fish species, especially cod fish scallops and shrimps are the major items for export, and represents by that the main source of hard currency to the "Sevryba" association and her member enterprises.

*4.2 Organisational changes in "Sevryba" through the reform process : Structure and decision making nodes in the process.*[3]

As noted earlier the fishing industry have had a central place in the food supply in Russia/Soviet Union like in other nations for hundreds of years. But the development of the fishing industry have to a much larger extent been subject to severe central planning and control in Russia than in other countries.

Through the period up till 1970 several economic reforms was implemented, but only minor organisational changes in the fishing industry followed as a direct consequese of these. But in 1973 the central adminstration introduced a new system called the *all union production association (VPO)*[4], so called obedineniie, as the industrial organisation of the future, (Dyker 1992 p. 60) :

> *"This created a highly complex system of sub-intermediate level, in which the norm was so called* ***production*** *associations to group together fairly small numbers of associated enterprise, which the latter sometimes losing their juridical independance, and* ***industrial*** *associations taking over the role of of the old glavki".*

The aim of forming these (obedineniie) associations was to improve the industrial performance, especially in the areas of labour productivity, quality, costs and use of advanced technology (Gorlin 1974). Figure 1 shows the structure of the economy and the decision lines in the fishing industry after the 1973 reform.

As the figure shows the system is built up after a model consisting of several levels both in the vertical and horizontal direction. But very simplyfied the hierarchy is basically consisting of six vertrical levels ; the communist party/presidium (CPSU), the Council of Ministers, the Planning Commitees, Ministries, industrial associations, and the production units.

In this structure the party had a superior position as the formal instance both executive and political decision maker. Nove (1986 p. 7) has described this fact as following :

> *"The politbureau is at the same time the supreme arbiter of politics and the board of directors of the USSR Ltd., the largest firm in the world".*

The production associations became a very common pattern of organizing the fishing industry throughout the entire union, and by this they took over most of the task from the directorates (Glavkis) organising the most important sea basins. According to Sysojev (1974 p. 49) the following associations (VRPOs) [5] was established as a consequence of the 1973 reform :

(i) VRPO "Dalryba", for the far East

2. The information presented in this passage is mainly based on information official data presented by Sevryba.
3. This part is based on two main sources : Sysojev, N.P. Economics of the Soviet Fishing Industry, and Davidsen, T. An historical overwiew of the USSR/Russian seafood Industry.
4. VPO ( Vsesojuznoe Proizvodstvennoe *Obedinenjie* )
5. VRPO - Vsesojuznoe *Rybnoe* Proizvodstvennoe Obedineniie

(ii) VRPO "Zapryba", for the Baltic sea areas

(iii) VRPO "Azcherryba[6]", for the fisheries around the Azov sea and the Black sea

(iv) VRPO "Kaspryba", for fisheries in the Caspian sea area

(v) VRPO "Sevryba" ("Northfish"), for fisheries in the north western Russia.

VRPO "Sevryba" consisted in broad of the enterprises and organisations composing the former Murmansk sovnarchoz [7] beeing the main part of the fishing industry in the Murmansk, Arkhangelsk and Karelia regions. In this period most of the seafood was probably exported by the organisation Sevrybsbyt through the three foreing trade organisations V/O Lenfintorg, V/O Prodintorg and V/O Sudoimport (Anon 1971).

As earlier noted one of the reasons for this reorganisation was to give the ministries and planning organisations more time to deal with the over all planning and control and hence transmit the the more "day to day" like tasks to the industrial associations.

> *"The rational is that the associations are better qualified than central planners and ministries to make planning and resource allocation decisions at the enterprise level, because associations are closer to the sources of information on which these decisions are made".* (Gorlin 1974 p. 5).

Even though the party have executed great power throughout the differrent levels in the decision process to the industrial organisation and single enterprise, the Primary Party Organisations (PPOs) do not normally have the over all responsiblity for the economic behaviour of the single enterprise any more.

> *"Most political scientists agree that the power of the PPOs is limited and does not strongly influence the operation the Soviet enterprises"* (Gregory & Stuart 1986 p. 157)

In addition to the political level the different planning organisations have played a very important role by instructing and supervising the industrial associations. In particular the state planning commission Gosplan have had great impact to the process of decision making and control on production (figure 1).

In the planning of production the top political planning and executing level have received help and input from amongst others the planning organisations, the branch ministery (ministry of fisheries in the RSFSR) the industrial organisation "Sevryba" and the different member enterprises. Through this process the planning organisations have been able to submit instructions leading to a total satisfaction of the all union demand for products and services, in this case seafood. The taut plans have been very detailed even down to the single enterprise both related to input and output and the pricing of the commidities and labour all through the process. Freris (1984 p. 164) has stated as a conclusion on his study of the soviet enterprise that :

> *"....There is every indication that the degree of centralisation is increasing both in terms of the growing role of associations and in terms of the concentration of production in the hands of a smaller number of enterprises and/or associations. An analytical approach of the behaviour of the firm must therefore consentrate even further on the role and games of the planners and the planned and the "unofficial" degree of freedom that the enterprises either are allowed to enjoy or manoeuvre themselves to enjoy".*

In figure 2, the arrows shows the direction of the directives and instructions (the weighted arrows) and the basic information or feedback from the enterprises and industrial association stating their estimated production for the next period of planning and also statistics from the historical production[8]. As noted earlier in this chapter, the enterprise havethe possibility to influence the plan demands through their feedback to their supervisory instance even though the command lines points in one direction only. This because the process of setting the plans goes through a iterative process between the relevant instances until the total needs (both locally and on republic/union level) is satisfied.

From 1987 to 1990 the reorganisation and reform processes have led to several formal changes of the organisation of the seafood industry in the Soviet Union and Russia. In 1990 the association "ARP Sevryba" was established. The association

6. Have later changed the name till Yougryba
7. Sovnaschoz was an earlier form of industrial organisation (1957) attempting to change the Soviet planning scenario from a ministerial to a regional basis.
8. The statistics is delivered to the ministry of statistics Goskomstat who collect and refined/accumulate tem for use both for control and planning purposes.

was now consisting of member enterprises (voluntary membership) and each of the enterprises was their own juridical person. Figure 3 shows how the association was (and still are) organised. As the figure shows "Sevryba" was organised into a self supplying structure consisting of vertically or horizontally integrated enterprises delivering different kind of input to each other. After 1990 the advantage of this type of formal structures do not have the same significance. The main reason for this is the changes in the impact of the centrally planning system.

One of the consequences is that "Sevryba" now is much more independant in relationship to central bodies, especially the former ministry of fisheries. One of the important changes is that the former plan demands have been substituted by state orders. Now the ordering institution have to compete with other (potential) buyers on a contract basis. This means that the single member company *in principle* is free to select buyers and vendors based on their own needs and criterias for price and quality etc. But still "Sevryba" do have an important function as a coordination element and also to a certain extent an intermediate link between the single enterprise and the central authorities. One of the important functions of "Sevryba" is the administration and distribution of quotas. It is interesting to note that "Sevryba" seems to have the responsibility both for member and non menber enterprises in this case, and both processors, transportation, and fishing fleet enterprises are "granted" with quotas. This gives a unique power to the "Sevryba" organisation and hence gives the membership (and obedience) a special value.

### *4.3 Sevryba as an exporter - motives and constraints*

So far in this presentation nothing have been said explicitly about the reform process and its impact on the foreign trade. Some elements of this aspect will be briefly discussed in this chapter. One of the most important factors to keep in mind when discussing the export performance of "Sevryba" and her member enterprises, is that the over all goal has been and still are, to provide the domestic market with (sea)food. Further there are two more factors that also plays an important role and seems to have a significant impact on the export behaviour of the enterprises. These are the enterprises need to operate on "khosrachot[9]" basis on the one hand and their need for foreign currency and technology on the other hand.

As indicated earlier, the volumes of the total fish catch mainly consists of the pelagic species. These are low priced products and does, with few exceptions only, go to the domestic market for consumption. According to "Sevryba" cod represents only 6 -10 % of their total annual catches. Estimated from the official total catches for "Sevryba" in 1990 this constitutes about 96.000 - 160.000 thousand metric tons. Primary results indicate that cod and haddock (and also fish oil, scallops and shrimp) represents the main items of export. As regards the cod (and other whitefish) it is by the russian enterprises evaluated equivalent to foreign currency. The importance of codfish as an export commodity is supported by studying the export and import statistics for the former Soviet Union. So far we are only able to present the foreign trade between Norway the former USSR. Figures 4 and 5 show the trade pattern as related to species.

It must be emphasised that the trade pattern shown in figures 4 and 5 only consists data about trade between Norway and the former Soviet Union. In this bilateral trade it can be fair to say that the trend is like describes above. More generalised one can say that high value products are often exported out of the former USSR to generate hard currency earnings.

But even though the demand and need for hard currency is strong in Russia, it is not necessarily so that the enterprises in Russia finds it favourable to do these earnings. This is connected to the legislation on foreign trade and taxation of foreign currency. The new legislation regulating the foreign trade have in principle provided the enterprises with less stringancy during the last 3 years. One important factor is the abolition of the plan demands for production and delivery to "dedicated buyers" which gives the enterprise the possibility to choose whether they want to sell to a domestic or foreign buyer.

Selling to a foreign buyer would generate foreing currency and lead to the possibility of buying other and lower priced seafood for distribution to the domestic market, or buying new technology for catching, processing of seafood. But at the same as the legislation opens up for foreign trade they also creates new barriers. One of these are the law on foreign currency and taxation which gives the local and central bodies (in practice) the right to "withdraw" 50-90 % of the currency earnings. This is one of the many contradictions that the "new" russian industry have to face in their new economic system. Like in other countries the industry seeks to adapt to the environment in order to maximise their (economic) perfomance. And it will indeed be interesting to watch the future development of the industry.

9. self financing - without governmental financial support.

## 5. CONCLUDING REMARKS

During this brief presentation of "Sevryba" and the development of the Russian economic system there are only presented a broad picture of the scene. So far it is hard to say if the export performance of "Sevryba" will or can affect the European market for codfish, due to its limited quotas of North Atlantic cod and other whitefish. At present the main commodities within the whitefish export are either fresh chilled H & G fish or frozen (cod)block fillets. The block export represents a minor contribution to the total supply to this market. On the other hand large amounts of fresh chilled cod have been exported to (Northern) Norway during the last years, and a change in this pattern could certainly harm the seafood industry based or partly on these landings, but there is no trend towards a negative shift in this trade. So far the russian industry seems to find alternative adaptions to the potential legislative barriers to export which speeds up the export rather than limiting it.

RÉSUMÉ

*Il existe des contraintes internationales et nationales tant au plan économique qu'au plan social dont doivent tenir compte des producteurs pour développer leurs activités. L'objet de la communication est d'identifier ces contraintes et de préciser les modalités de développement de ces activités en fonction de trois types de développement :*

1. *Type de développement villageois dont les objectifs consistent en l'augmentation de la production et en l'amélioration des revenus de la société rurale.*
2. *Type de développement industriel qui ne peut éviter certaines contraintes nationales et internationales.*
3. *Type mixte qui combine les deux premières approches.*

*Dans tous les cas, cela induit des comportements des producteurs différents et une prise en compte de l'hiérarchie des contraintes différentes. L'étude de cette diversification du système de production va permettre d'analyser et d'approfondir davantage les problèmes de développement dans le monde rural d'un pays du Tiers Monde à économie typiquement agricole orientée vers les cultures de rente. L'identification de nouveaux paramètres contribue à infléchir les styles de vie et les styles de développement. Quel type de planification exige cette nouvelle méthode ? Quelles nouvelles manières d'occuper l'espace et le temps, elle requiert ? Comment elle ne peut être mis en oeuvre sans une certaine indépendance technologique ?*

ABSTRACT

*Producers have to account for international and national limitations from the social and economic point of wiew to work out these activities. The purpose of this paper is to describe conditions for the development of these activities according to three models :*

*1. Rustic model with objectives to increase production and to improve rural incomes.*

*2. Industrial model with international limitations relative to the market.*

*3. Model mixing to the aspect before.*

*Producers must take different attitudes in the face of these situations. The diversification of the production system can be analysed to understand the increasing problems of development in the Third World agricultural economy. The identification of new parameters enables us to find means of subsistence and models for development. What is the type of planification required for the new system ? How can the necessary time and space be taken ? What to set in practice without technological independence ?*

## 1. CONTEXTE ECONOMIQUE ET POLITIQUE ET ENJEUX

L'indépendance, **en 1960**, a hérité d'une économie fondée uniquement sur les cultures d'exportation. Les événements de **1972** ont complétement changé les lignes politiques, financières, économiques et sociales qui ont été réaffirmées, **en 1975**, par les nationalisations, les restrictions de change, les investissements pour l'industrialisation et les restructurations sociales et administratives.

Mais l'inefficacité des mesures prises et les revers de la dépendance économique issue des conjonctures internationales de la décennie 70, précipitent le pays dans une crise profonde. Depuis 1980, l'application de la politique de stabilisation et d'ajustement économique, politique dictée voire imposée par le Fonds Monétaire International et la Banque Mondialepour assainir l'économie et restructurer le système de planification ne fait que contribuer à l'extension de l'appauvrissement des différentes couches sociales particulièrement les plus démunies aussi bien en milieu urbain qu'en milieu rural. Et, les difficultés s'amplifient davantage et la situation économique et sociale se détériore durant l'année 1990. Ce qui précipite les mouvements populaires de 1991 qui mettent un terme au régime mis en place depuis 1975.

## 2. PROBLEMATIQUE

Face à la détérioration des conditions de vie à Madagascar, il s'avère nécessaire de déterminer les lois qui président à la paupérisation en milieu rural afin de proposer des pôles de développement aquacole qui permettent aux ruraux de lutter contre cette tendance. A Madagascar, l'appauvrissement se manifeste de différentes manières selon les régions et les particularités des populations concernées. Cela justifie le choix d'un type de combinaison d'activité (aquaculture et diversification) dans une zone géographique de l'Est du pays.

## 3. METHODOLOGIE

Dans cette perspective, il s'agit d'identifier les groupes cibles et de coordonner la mise en oeuvre des opérations de développement d'une façon effeciente et adaptée au contexte du pays. La méthode consiste à élaborer une base de données de manière à disposer d'indicateurs qui permettent de repérer les changements de comportements et d'habitudes des producteurs ruraux afin de mieux intégrer dans les méthodes culturales les activités aquacoles en milieu rural. L'investigation s'inscrit donc dans le cadre de la dimension sociale de l'organisation-développement des activités aquacoles du monde rural. Les objectifs en sont multiples :

- Analyser l'impact de la politique de redressement sur les conditions de vie des producteurs ruraux.
- Etudier les réactions des paysans ruraux face à la dégradation de l'environnement socio-économique.
- Essayer d'analyser le processus de repli du monde rural sur une économie de subsistance.

- Elaborer des pôles de développement à l'intention des producteurs ruraux et en adéquation avec leurs besoins.

La recherche donnera des réponses aux objectifs ainsi posés et, à travers les résultats obtenus, proposer des actions de développement. Les pôles de développement identifiés doivent répondre aux potentialités ainsi qu'aux contraintes observées. Il s'agit de l'intégration de l'aquaculture extensive et diversifiée dans les activités agricoles, qui peut se présenter sous divers types de développement :

- Type de développement villageois dont les objectifs consistent en l'augmentation de la production et en l'amélioration des conditions de vie de la société rurale.
- Type de développement industriel qui ne peut éviter certaines contraintes nationales et internationales.
- Enfin, Type mixte qui combine les deux premières approches.

## 4. RESULTATS

**Les politiques de développement du régime en place, d'une part, et le redressement économique** du Fonds Monétaire International et de la Banque Mondiale, d'autre part, n'ont fait que contribuer à **l'appauvrissement de certains groupes sociaux ruraux menacés de marginalisation :**

- Depuis l'application de la politique de libéralisation de l'économie en 1983, le taux d'inflation se stabilise à deux chiffres.
- Les dévaluations successives du franc malagasy ont fortement réduit les pouvoirs d'achat des différentes couches sociales et plus particulièrement celle des producteurs ruraux.
- Les fluctuations des cours mondiaux des produits de rente ont affecté véritablement les conditions d'existence des petits producteurs ruraux.
- A tout cela s'ajoute l'accroissement rapide de la population qui accentue les difficultés en milieu rural.

Le poids des contraintes institutionnelles ( programme d'ajustement structurel, legislation, insécurité... ) se traduit par la détérioration des conditions de vie et surtout par le repli du monde rural sur une économie de subsistance. Ces phénomènes constituent des blocages à toute forme de développement.

Toutefois, des résultats tangibles ont été obtenus par la mise en oeuvre de la politique d'assainissement économique malgré certaines conséquences néfastes sur les populations rurales. De plus, des changements se manifestent dans les comportements et les habitudes des acteurs économiques et se manisfestent par :

- L'émergence d'un certain esprit d'entreprise au sein de la population rurale, le développement d'initiatives privées et la prise en charge des responsabilités.
- L'éveil d'un certain esprit de développement régional, généré par des flux migratoires de la ville vers les campagnes :(retour à la terre, apport de techniques nouvelles...).
- De façon induite, une modification profonde des comportements culturels : (désaffection de certaines coutumes et traditions...).

Ces changements de comportements et d'habitudes des paysans ruraux se traduisent par des actes concrets qui peuvent constituer des éléments de base pour l'intégration des activités aquacoles en milieu rural traditionaliste. Ils essaient de diversifier leurs activités agricoles. Ils appliquent les méthodes culturales plus performantes et efficaces. Ils commencent à associer l'élevage à l'agriculture pour tirer profit de leur complémentarité. Les résultats de l'évolution des productions témoignent les efforts réalisés pour diversifier le système productif. Mais les rendements restent souvent aléatoires au profit des calamités naturelles et faibles par manque d'encadrement. (Graphiques de l'évolution des différentes catégories de produits agricoles durant la période 1985-1990).

## 5. CONCLUSION

Ainsi, la prise en compte des contraintes sociales et économiques constitue un des éléments de base de l'étude pour définir et orienter les actions de développement de l'aquaculture extensive et diversifiée en milieu rural. L'intérêt

nouveau des producteurs ruraux pour certaines innovations techniques marque la fin des mythes sur les sociétés traditionnelles rurales et économiquement sous-développées. La situation qui prévaut pour les producteurs ruraux de la région orientale malagasy constitue un des cas d'opportunité de l'application des actions de développement économique en milieu rural. Cette approche permet de mieux apprécier la logique paysanne et les réalités socio-économiques des sociétes rurales traditionalistes afin de déterminer leur capacité tant géographique qu'écologique à accueillir des actions de développement. Ce type d'approche présente l'intérêt de faciliter le passage de la théorie à la pratique en s'inspirant de l'observation de François Perroux : "Le développement, c'est l'organisation". C'est seulement à cette condition que les pays à économie sous développée ont une véritable chance d'assurer leur développement économique.

ABSTRACT

*A recent conference on the state of the art in salmon demand studies (DeVoretz, 1990) heard several participants criticize the long-standing findings derived from aggregate time-series data. With the aid of the Canadian 1986 Food Expenditure Survey, we will refocus Canadian fish demand studies at the retail level using cross-sectional household expenditure data. The major aim of this study will be to provide the first systematic investigation of the demand for several Canadian individual and aggregate fish products at the retail level using household Census data.*

*Our major findings include an estimated meals equivalent model which agrues that the life cycle stage of the household is central to understanding Canadian protein expenditure patterns. In sum, in this augmented model the traditional economic variables of price and household are equal in importance to head of household age and family size and composition in explaining protein demand.*

## 1. AIMS AND OBJECTIVES

Several recent studies covering a variety of protein products have estimated demand functions utilizing household level data[1]. This study will add to the existing literature by estimating the Canadian demand for fish, dairy and meat products at the household level. In addition, we will propose a family life cycle model to measure the impact on protein demand of age, place of birth, education, marital status, and other household features. We employ this approach since the

1. These studies include : Heien and Wessells, 1988 ; Capps *et al*,1985 ; Moschini and Meilke, 1989 ; Bewley and Young, 1987 ; Burton and Young, 1992 : Haden, 1990 ; Chesher and Rees, 1987 ; Hassan and Johnson, 1977 and Chesher, 1991.

omission of these life cycle variables leads to econometric problems as well confusing the roles of taste and economic variables in understanding the change in Canadian protein demand. For example, Atkins, *et al.* (1989) argue that the Canadian debate over changes in the demand for beef is clouded by imprecise definitions of key variables. This study through the use of panel data will be able to provide a more satisfactory definition of key household variables. Furthermore, R.L. Thomas (1987) outlines the inherent econometric problem if we omit household economic-demographic interaction terms ;

*"The major difficulty in estimating total expenditure elasticities from cross sectional data is the existence of a number of nuisance variables.....Possibly the most important of these (nuisance variables) are size and composition of the households."* (R. Thomas,1987 p. 19)

The difficulty in estimating this relationship of taste changes to household characteristics is illustrated by Burton and Young (1992) when they state :

*"Our methodology...does not allow one to determine the underlying causes of taste changes in consumer preferences. But many factors could be suggested to explain changes in taste. These might include changes in household constraints....., in demography (age, sex, and ethnic composition of population) and the structure of the outlets of meats."* (Burton and Young,1992 p. 10)

This paper will directly measure the effects of these individual demographic factors in the changing Canadian demand patterns for protein source products.

## 2. METHODOLOGY

The logic of the method is as follows. First, under the assumption of fixed relative prices Engel curves or total expenditure functions will be estimated for three major (meat, fish and dairy) Canadian protein groups and a residual food category. Next, prices will be introduced and share equations will be estimated under an *Almost Ideal Demand System* (hereafter, *Ideal* ). Restrictions on the share equations will be imposed to test for rationality of the Canadian household. In particular, we will test the demand system for homothicity, homogeneity, concavity and symmetry in prices. In addition, under the total expenditure or Engel curve analysis the adding up restriction will be imposed.

## 3. LIFE CYCLE AND ENGEL CURVES

We initially describe the life cycle food/protein consumptionpatterns of a Canadian household *circa* 1986 with the aid of adjusted Engel curves. Standard Engel or expenditure curves will be augmented with demographic variables to capture the life cycle effects on food consumption *patterns*. The life cycle approach argues that demographic forces alter the levels and expenditure patterns of households (Marr and McCready, 1989). One demographic force ; age, has particular relevance to this food expenditure study. It is often argued that age is a proxy variable for changing tastes within the household especially with respect to protein source foods (i.e. meat, fish, and dairy products). Both the food category (meat, fish or dairy) and place of purchase (away from or at home) are argued to be systematically affected by age. In addition, aging directly affects family income. Finally, marriage and family formation are directly related to age. In sum, age can interact with income (savings), marital status and ultimately family size. All these demographic features vary systematically throughout the family's life cycle and could have an independent effect on food expenditure levels. Table 1 highlights the importance of the age variable in the family food expenditure decision.

First, we note from Table 1 that the typical Canadian household spends eight times more on meat than on marine products over its lifetime. Moreover, as the representative Canadian household head ages ; meat consumption rises (on average) by 1 per cent (of the food budget) for each elapsed 5 year interval. Contrary to conventional wisdom meat consumption does not decline with age, but peaks at age 50 at 18 per cent of total food expenditures. On the other hand, family fish consumption experiences two discrete growth spurts at age 35 and after 50 years of age. However, fish expenditures in the family budget always remain significantly below meat's share of the food budget.

One standard question emerges from an inspection of Table 1. What portion of these changing life cycle patterns for meat and fish consumption are due to demographic forces (family size, age of head, education, marital status, number of dependents) and how much of these differences are owing to the economic forces of relative prices and income ? Estimating food share equations at different stages in the life cycle will identify the relative importance of demographic forces (e.g. age, family size, location,etc.) and economic forces (relative prices, income) in explaining food consumption patterns. Our stylized household model presented below will expand on our arguments for the timing and direction of these demographic effects.

Figure 1 depicts the typical life cycle consumption pattern for a hypothetical food commodity. Initially holding family income and relative prices constant and starting with a unattached male head of household aged O, the act of marriage and child rearing during the interval O-A increases the consumption of the (ith) good at an increasing rate. This rate of increase would be even larger if the household head were foreign born and assimilation occurred during O-A. At point A the household begins to mature and although family expenditure on the (ith) good will continue to rise, household size is fixed and for the foreign born consumption assimilation is almost complete. From B to C household size is constant with (any) older children assumed to still live at home. Finally, after age C is reached, total household consumption is reduced as dependents leave and the aging process continues and less food is required.

Now if there exists no interaction between the demographic variables and income then, superimposing the income effect on these demographic variables would leave the diagram unchanged[2].

However, we agree with Thomas (1987) and Chesher (1991) that there exists interactions between income and demographic variables. The two most obvious are when children enter the labour force and raise household income and when the opportunity cost of leisure of the parents is altered with more children. In the latter case, depending on the relative income and price effects the labour supply of the adult household members may rise or fall. Hence, income and food expenditures may rise or fall. Thus, we argue that demographic variables have a direct and indirect set of effects. The direct effects are unambiguous. However, the indirect effects especially on income are ambiguous and must be determined empirically via the inclusion of interaction terms in our model.

## 4. ESTIMATION MODEL : ALMOST IDEAL DEMAND

Deaton and Muelbauer (1981) argue for an Almost Ideal Demand system (*Ideal*) with restrictions to satisfy the properties of homogeneity, adding up and symmetry. This demand system which is owing to Working and Leser can be written as :

$$W_{it} = a_i + B_i \log (Y_t / P) + \Sigma G_{ij} \text{ Log } P_{jt} \qquad (1)$$

where :

$W_t$ is the ith expenditure share of product i in total expenditures and $Y_t$ is total family per capita income with $a_i$ and $B_i$ parameters to be estimated[3]. P is an index which in its linear approximation equals :

$$\text{Log } P^* = w_i \log p_i \qquad (2)$$

where $w_i$ is the mean of the budget share. Thus, the approximation of (1) now becomes (2)

A system of share equations (i.e. eq. 2) are then estimated to yield parameter estimates which in turn are converted into elasticities.

Estimating Engel elasticities requires that we assume that prices are fixed. This yields a budget share equation for a cross section (i.e.the subscript t is dropped) of

2. As long as the income effect is positive then given that age income profiles have the same slopes as the food age profiles the income effect will simply raise everywhere the age food profiles.
3. This imposes the restriction of homogeneity of scale.

$$W_i = a_i + B_i \log Y \tag{3}$$

When estimating Engel elasticities Philps (1983) argues that additivity (i.e. total shares equal unity) is the crucial restriction. Adding up requires that :

$$\Sigma W_i = 1 \text{ and this will occur if}$$

$$\Sigma a_i = 1 \text{ and } \Sigma B_i = 0$$

This implies that the (ith) good is a luxury if $B_i > 1$ ; a necessity if $B_i < 1$ but $> 0$ and inferior if $B_i < 0$.

When prices and income are free to vary and we estimate the entire food demand system we further restrict the system to satisfy symmetry ($G_{ij} = G_{ji}$) and homogeneity ($\Sigma_i = {}_1 G_{ij} = 0$). The adding up property will hold if $\Sigma_{i=1} a_i = 1$ and $\Sigma_i = 1$ and $B_i = 0$. Concavity or monotonicity are difficult to impose and harder to interpret and thus are omitted[4]. If the imposed conditions of additivity, symmetry and homogeneity empirically hold then the weak separability of our food group aggregations is valid. For our sample weak separability implies that non-food prices do not influence the household's consumption of meat, fish, dairy or the residual food products[5].

The computational formulae for the total expenditure and price elasticities are :

$$\eta_i = 1 + B_i / w_i \text{ and} \tag{4}$$

The Marshallian or uncompensated price elasticity of demand for good $_i$ is[6]

$$\eta_{ij} = d \log Q_i / d \log P_j = -D_{ij} + d \log w_i / d \log P_j \tag{5a}$$

or in terms of the share equation parameters

$$\eta_{ij} = - D_{ij} + 1/S_i [G_{ij} - B_i (a_j + \Sigma G_{jk} \log p_k)] \tag{5b}$$

where $D_{ij}$ is the Kronecker delta and $D_{ij}$ equals 1 when i=j and 0 otherwise. The estimates for $G_{kj}$, $G_{ij}$, $B_i$ and $a_j$ can be obtained from the estimates of the linear approximation of the full model i.e. equation 2.

## 5. DATA

The data source is the *1986 Family Food Expenditure Survey* which consists of two public use sample tapes. The detailed file contains the quantity, expenditure, place of purchase (home, store, restaurant) and week of purchase for 240 individual food categories compiled by the (stratified) randomly selected 10,919 households. The summary file contains the demographic variables collected under the interview process. The actual expenditures on the 240 individual food categories were recorded throughout Canada over the entire year thus, insuring a reasonable amount of price variation. Households (both individuals and families) in different monthly sub-samples kept expenditure records for two consecutive weeks. The summary and detailed versions of the food expenditure tapes were merged by the authors to facilitate estimating the food share equations[7]. The key descriptive statistics are reported in Table 2.

The typical household in the *1986 Food Expenditure Tape* closely conforms to the 1986 Census values. The average household had 2.7 members with 55 % of these units located in large urban areas and 19 % in Quebec and 24 % in Ontario. Sixteen percent of the head of households were foreign born while 25 % of the heads had greater than secondary education. Females headed only 29 % of the households.

4. See Chalfant,Gray and White (1991, p.478) for a more complete rationale for omitting these restrictions.
5. If the imposed conditions do not hold then this implies that we have an omitted variables problem i e. some non food price should have been included in our system.
6. See Green and Alston (1990, p.443) for this and the compensated price elasticity derivations.
7. This merger was required since the summary tape contains the relevant household demographic variables while the price and household expenditure data are contained on the detailed tape. Given the fact that both tapes continued one common vector for the household ID number the merging was possible.

The average household total food expenditure was $148.77. Their food budget shares were 20 % for meat (i.e. beef, pork, veal, chicken and turkey) ; 2.5 % for fish cod, halibut,tuna and salmon), 17 % for dairy products (cheese, milk, butter and ice cream) with 58 % of the remaining food budget spent on other food categories. There existed substantial variation in the key prices for dairy, fish, meat and the residual group ( i.e. DP,FP,MP,RP ) as well as large variations in household total food expenditures[8]

Several data problems were encountered. First, many households reported zero consumption for some of the 240 detailed items. Hence, to reduce this problem we aggregated data into three major protein groups (meat, dairy and fish) and a residual food category[9]. To aggregate we summed over all the household's purchases within that commodity group from the detailed tape. This procedure still left approximately 50 % of the surveyed households with no fish consumption over the two week period. For the remaining groups ; meat, dairy and residual food the number of zero consumption level households were well below 10 % of the total households. Since the price variable was computed as expenditure divided by quantity we had to adjust for zero consumption levels. When a household had zero expenditures for any aggregate we used a regression procedure owing to Heien and Wessels (p. 221)[10].Thus, we were able to use all 10,919 reporting households in every regression.

Other constructed variables included an estimate of the number of meals served in the household. This variable was defined as a meals at home equivalent and was computed as the ratio of all meals actually served at home divided by a multiple of 21 meals. Thus, if the average household with 2.7 members served the maximum (21*2.7) or 56.7 meals at home per week then the ratio equalled unity[11]. The actual value for the meals equivalent variable was 1.01. This indicates that there was no significant trend to eat meals away from home *circa* 1986 in Canada and contradicts the reported descriptive statistics of Goddard (1983, p. 289-290.). We will reflect on this phenomenon in detail in a meals equivalent model of consumption. We also define a spouse at home variable to capture the opportunity cost of the labor involved in preparing meals at home. If a spouse was present in the household and worked less than 20 hours outside the home the dummy variable for spouse at home equalled unity. Otherwise, the dummy assumed a zero value.

## 6. ESTIMATION AND TESTING

### *6.1 Expenditure Elasticities*

We estimate this system with Zellners Seemingly Unrelated (*ZUR*) technique since the adding up criterion implies that shares are interrelated[12]. We report our results for the *Ideal* system with and without demographic variables[13].

Panel A reports the calculated expenditure elasticities for the four chosen product groups. These expenditure elasticities were derived from the estimated share equation (i.e. equations 3 and 4) parameters without demographic variables. Only meat is a luxury with an elasticity significantly above unity. All the remaining groups are either below unity and necessities (fish and dairy) or normal i.e. residual food group.

Following Thomas (1987) and Chesher and Rees (1987) we correct for omitted variables and include the intercept terms for age and family size and the demographic interaction variables : i.e. Age*Exp and Family size*Exp. As expected with omitted variables the adjusted expenditure elasticities drop significantly (see Panel B) with the inclusion of demographic

8. Following Chesher (1991) we plotted income against total food expenditures. The large variation in total expenditures by household income is disturbing since this no doubt reflects the fact that higher income families hold larger inventories. Thus, the greater variation in food expenditures for the two surveyed weeks as household income grew.
9. We could have omitted the residual food category and invoked weak separability vis a vis any food in the residual group and meat, fish or diary products. This is an empirical question. However, the prevalence of meat and potatoes ( with gravy) as a stable food dish in Canada intuitively argues against separability.
10. We estimated the following equation : $Pi = a + B^{*}$ income $+T^{*}_{jR + ik^{*}Q1}$ where R=1 if not Atlantic province and Q is quarterly dummy.
11. Meals equivalent was computed as : [(a*21*family size)+guests-(a*restaurant)]/[a*21*family size] where a=2 for the two week coverage ; Guests = meals served at home to guests,boarders or domestics ; Restaurant= the number of meals household members ate in restaurants the previous month divided by two.
12. There is no obvious simultaneity since the purchase of any (ith) group does not affect income.
13. In order to estimate every food groups expenditure equation the residual equation was first omitted from the system and then the fish equation was omitted in a subsequent estimation.

variables. Now the expenditure elasticities for meat, and dairy products are less than unity indicating that these food groups are necessities. Fish and dairy goods are inferior given their negative expenditure elasticities. Using a similar model for the United Kingdom with household panel data Chesher and Rees (1987, Table 4, p.446) also, report very low meat income elasticities of.21 and.31. On the other hand, Chesher (1991) reports a positive total expenditure elasticity for U.K. fish demand however, his demographic arguments were insignificant (Table 6.5, p. 63).

### *6.2 Complete Model*

Given the large regional and seasonal variation in prices (see Table 2) the assumption of constant prices used to derive the above Engel or total expenditure elasticities is incorrect. In this section we report the findings for a complete *Ideal* model (equation 2) which includes prices. In addition, we (partially) imposed the restrictions of homogeneity in prices and income, adding up and symmetry[14] We also estimate the system under the *ZUR* technique for reasons given above. This produces estimates which are equivalent to maximum likelihood results.

Following the traditional approach in the literature (Philps, 1983) for treating demographic variables we now decompose the household's family size variable into three age groupings (SPEND or ages 0-5, 6-16,17-65 ) to partially reflect the household's stage in the life cycle. The head of household's gender (sexh) and education (educat) are also included. In addition, we add regional (R) and seasonality (Q) variables. The geographical variables include an urban/rural (City) dummy, dummies for maritime versus hinterland divisions (R) and a foreign birth status (birth) dummy. The basic model's parameter estimates for the share equations are reported in Table 4.

## 7. RESULTS : COMPLETE MODEL

Table 4 reports the Marshallian uncompensated own price and total food expenditure elasticities. All the uncompensated own price elasticities are approximately unitary or less except for the residual food group. The demand for meat is inelastic (-.77) while fish and dairy are near unitary elastic. All food commodity groups are luxuries with respect to total expenditure variations. We now turn to a comparative analysis.

### *7.1 Meat*

Our meat (i.e. beef, pork, veal, chicken and turkey) own price elasticity is well below unity (-.77). Hassan and Johnson (1977, Table 1, p. 57) estimate with earlier Canadian panel data (i.e. *1974 Food Expenditure Survey*) much larger own price elasticities for various meat products. In general however, studies using Canadian time series report own price elasticity estimates for meat similar to our findings. With Canadian time series data (1968-1986) Atkins *et al.* report Canadian own price elasticities in a range of -.5 to -.7 ( Table 2,p.520). Chalfant, Gray and White (1991) for a longer Canadian time series (1960-1988) also support our findings. Their estimated (Table 2, p.485) Marshallian demand elasticities were respectively :beef -.95 ; poultry -.9 and pork -.7.

The total expenditure elasticities for meat in Table 4 is higher under the full *Ideal* model (1.78) then under the earlier Engel estimates (1.27) which assumed constant relative food prices. Atkins *et Al.* (1989) found negative Canadian income elasticities for meat (Table 1, p.516) when they used real income per head for the 1968-1986 period and subsequently question the relevance of this times series income measure. Chalfant *et Al.* (1991, Table 3 Part A, p. 486) using Canadian time series data report similar (to our Table 4) total expenditure elasticities for meat (beef=1.6). However, Chan (1983) using Canadian time series data for 1949 to 1969 with a double logarithmic static model report a low range of meat income elasticities of.02 to.44 (Table 4, p. 45).

14. Since we employ Zellner's Seemingly Unrelated approach we must drop one equation. Thus, the adding up criterion can only be indirectly satisfied by imposing simultaneously homogeneity i.e. 1-sum of constant terms = 0. Several cross price elasticities are also lost and hence the restriction is limited to three (out of six possible) pairs of cross price parameters.

*7.2 Fish*

This study's estimated fish own price elasticity ( i.e. -.97) is within the range reported by Hassan and Johnson[15]. However, DeVoretz's (1988) study which reviews a variety of Canadian fish products cites generally higher own price elasticities (-20 -fresh to -1.4 Pink canned) for estimates at wholesale level with time series data[16].

In addition this study found fish to be a substitute for meat (.467) and a complement to dairy products (-.98) and other foods (-2.5). In their Canadian times series findings Chalfant *et al.* report (Table 4, p. 486) fish to be mild substitutes (.3 to.08) for a variety of Canadian meat products.

This study's total expenditure elasticities for fish is normal (1.43) and considerably larger than the Engel estimates (.78) reported in Table 3. Previous Canadian studies report a wide range of values for income elasticities. DeVoretz (1990, Table 1, pp. 90-92) cites a range of salmon income elasticities from 9.8 to.49 depending upon the specific specie product type. Chan (1983) using Canadian time series data (1949 to 1969) with a double logarithmic static model reports a range of fish income elasticities of -.02 to.49 (Table 4, p. 45).

*7.3 Dairy Products*

In this study dairy products obtained an own price elasticity of -1.00 which is well above the price elasticity values (-.06 to -.90) reported by Hassan and Johnson for Canada in 1974. In addition, this study found that Canadian dairy products were gross complements for fish (-.98) and all other foods (-1.33) while being a mild substitute to meat (.189). Total expenditure elasticities under our complete model for dairy products are normal (1.23) and considerably larger than the Engel estimates (.89) reported in Table 3. Chan (1983) using Canadian time series data (circa 1949 to 1969) with a static double logarithmic model cites a range of income elasticities of -.047 to.33 (Table 4, p. 45) for dairy products.

Non-Economic variables :

We argued earlier that life cycle features of the household would also affect food consumption in Canada. The standard version of the life cycle model captured few demographic effects[17]. Thus, we must incorporate more fundamental changes in our household model. First, following Goddard (1983) we measure the number of meals served at home and eaten away. Next, we incorporate the effects of spouse at home on food consumption patterns. Also, the foreign born assimilation phenomenon is more fully captured with a years in residence variable. Finally, an F-test is conducted for various age groups (for head of household) to detect household structural changes at different epoches.

## 8. MODERN HOUSEHOLD MODEL

Table 5 presents the results for our agumented model which argues that the household food consumption level depends on the presence or absence of a full time spouse in the household *ceteris paribus*. The process occurs in two stages. First, with a spouse at home the opportunity cost of meal preparation falls and raises the consumption of labour intensive foods. In addition, the number of meals prepared at home will rise with a spouse at home and this in turn will influence food consumption. Table 5 summarizes these findings. The elasticity measures generally indicate a uniform pattern. With a one percent rise in the number of at home spouses less meat (-.73) and less of the residual food category (-.42) is served per meal equivalent. On the other hand, with a one per cent rise in households with at home spouses more fish (.45) and dairy products (.17) are eaten at home. Given the strong significance of these heretofore omitted household variables the predicted decline in the economic arguments appears. Total expenditure elasticities fell substantially for all food groups but, all food products remained normal. The own price elasticities remained constant for all products in the augmented model except for the residual food category. The pattern of substitution (or complementarity) remained in the augmented model but in general the cross price effects fell.

15. Aggregate fish is defined as fresh, frozen or smoked cod, halibut and salmon and canned salmon and tuna.
16. This result is counter intuitive since we expect higher own price elasticities as we move up the distribution chain from the wholesale level to the retail level
17. Results available upon request.

Given the general strength of this augmented model's spouse and meal equivalent variables we now explore the effects of the remaining key household characteristics of age, foreign birth status and education. A one percent rise in the number of households with heads aged 35 or more leads to a decline in each food group with the smallest decline for fish (-.16 %) and largest decline in dairy products (-1.22 %). Increased growth in the foreign born in Canada's population will raise meat consumption and lower all other types of food consumption[18]. Foreign born assimilation or duration in Canada has a differential effect on food consumption. The longer the foreign born reside in Canada the less meat, fish and other food products are eaten[19]

Finally a comparison of the first three rows of Table 5 (i.e. economic elasticities) *vis a vis* the last five rows (i.e. demographic elasticities) indicates that the relative impact of spouse at home, education of head of household and foreign birth status equal or exceed the own price or cross price effects. Only the total expenditure elasticities generally dominate the demographic arguments.

## 9. SUMMARY AND CONCLUSIONS

We first summarize the traditional results derived from the Engel estimates and then draw conclusions from the standard *Ideal* model. Next, we summarize the findings and implications of the meals equivalent model. The total expenditure elasticities initially had an upward bias (unrealistically) indicating that all food categories were luxuries. But when demographic variables were included absurd expenditure elasticities were obtained. Fish became an inferior good (i.e.negative elasticity) with meat, dairy and other food products being strong necessities. The complete Ideal model with both prices and standard household demographic arguments yields generally price inelastic (meat) or near unitary elastic demand for other protein products (fish and dairy). The inelastic nature of meat indicates that fish and dairy products are not strong substitutes for meat. This is confirmed by the cross price effects with fish a weak substitute for meat (.47) and dairy products even a weaker substitute (.18). In sum, under the standard *Ideal* model meat has an inelastic demand with no real substitutes[20]. The total expenditure elasticities are unrealistically high. It is theoretically unlikely that all food is a luxury (i.e. every elasticity exceeds unity). More specifically it is difficult to find evidence in the literature that the residual food category is income superior to meat, fish or dairy products. Finally, contrary to the literature the typical demographic arguments of household size or composition are trivial in this standard version of the *Ideal* model.

Our augmented model with both spouse at home and meals equivalent produces the theoretically expected values for both total expenditure elasticities (all approximately unity) and significant demographic arguments. In addition, the own price and cross price effects are generally stable indicating that the impact of the formerly omitted variables (meals equivalent and spouse at home) interact with household income and not relative prices. Thus, we conclude that the crucial life cycle effect to capture in the 1986 cross section is primarily the presence or absence of a spouse at home in the household. With a spouse at home then both household money income and the relative cost of meals at home decline. Family size and composition are now more accurately captured through a larger meals equivalent variable *ceteris paribus*. Other traditional demographic arguments, age and education obtain theoretically correct signs. Age reduces all food consumption but fish is reduced the least. Being a foreign born head of household in Canada alters tastes when compared to the Canadian born in favor of meat *vis a vis* the other protein source products. The duration in Canada variable indicates that assimilation with respect to the Canadian born consumption pattern occurs for only meat and dairy products[21].

The relative impact of economic and demographic variables can be deduced for the augmented model. Total expenditure elasticities still dominate with particular demographic effects important for individual products. For example, age and the

18. This does not imply that assimilation does not take place. The one percent raise evaluated for the elasticity measures the effect of more immigrants with the same average years resident in Canada.
19. Conversely the amount of dairy products consumed rises with longer residence.
20. Note the residual category is a complement.
21. Assimilation occurs only if the foreign born and the years in Canada parameters differ in sign. For example, more meat is initially eaten (.23) by the foreign born but as time passes less meat is eaten (-.004) each successive year by the foreign born.

meal equivalent variables have large effects on dairy and the residual food categories. Meat consumption is affected by spouse at home and birth place of the head. In sum, the cross, own price and income effects still dominate for every food category but just marginally in the dairy and residual categories[22].

# La pêcherie artisanale maritime des filets dormants à sole (*cynoglossus sp.*) en Casamance (Sénégal)

**Hamet Diaw Diadhiou**

Centre de Recherches Océanographiques de Dakar-Thiaroye (CRODT), B.P 427, Ziguinchor, Sénégal

RÉSUMÉ

*La présentation de la pêcherie artisanale en mer des filets dormants à sole (Cynoglossus sp.) est proposée. Les aspects liés à la pêche et à la ressource sont abordés. L'historique du développement de la pêcherie, les caractéristiques des engins de pêche utilisés et des marées, les captures, les rendements et les potentialités de la ressource sont cernés. Dans la dernière partie, les différents circuits de commercialisation sont identifiés et décrits. Mots clés* : Sénégal, Casamance, pêche, filets dormants à sole.

ABSTRACT

*The purpose of this paper is to present the frame fishing nets sole (Cynoglossus sp.) of the small-scale hand line sea fisheries. Its starts with the aspects related to the fisheries and an analysis of this resource. Then it goes on with a review of the fishery development, the characteristics of fishing gear, going out fishing, catches, output, resource potentialities. Finally there is an identification and description of the different sale channels. Key words* : Senegal, Casamance, fishing, frame fishing nets sole.

## 1. INTRODUCTION

La pêche de la sole en mer en Casamance s'est développée à partir des années 1984 avec l'existence d'un marché à Dakar (Diaw, 1985). Mais son essor remonte au début de 1986 lorsque les usines de crevettes de Ziguinchor ont commencé à

s'intéresser au poisson pour diversifier leurs activités (Deme & Diadhiou, 1990). Aujourd'hui, c'est un pêcheur sur trois qui s'adonne à cette activité. Depuis 1988, des pêcheurs s'installent en saison des pluies (de juillet à octobre) dans la zone située en aval de Ziguinchor pour pêcher la sole.

Les données utilisées pour écrire cette article sont tirées des résultats du mareyage de la sole du plus grand mareyeur de cette espèce installée à Kafountine. La consultation des carnets d'achat de ce mareyeur a permis de réunir des données sur le rendement par sortie de pêche des différents pêcheurs qui vendent au mareyeur.

Un programme fortran a été écrit pour sortir les résultats. Les figures d'évolution des rendements sont dessinées grâce au logiciel STATGRAPHICS.

Les objectifs de l'étude sont multiples. Il s'agit dans un premier temps de réaliser une analyse descriptive de la pêcherie pour dégager après des problèmatiques de recherches. Un autre objectif est la description des relations qui peuvent exister entre mareyeurs et usiniers d'une part et entre mareyeurs et pêcheurs de l'autre au niveau de l'accés à la ressource pour les usines.

Plusieurs aspects liés aux captures, à l'effort, aux rendements, aux potentialités ainsi qu'à la commercialisation sont abordés.

## 2. PRÉSENTATION DU MILIEU

La Casamance s'étend sur une façade maritime de près de 70 kilomètres du nord au sud (fig. 1). Son plateau continental est l'un des plus larges des côtes du Sénégal, il s'étale sur 54 miles. La superficie de ce plateau est de l'ordre 30 000 kilomètres carrés (Citeau et *al* , 1985). Les fonds sont constitués de sédiments meubles composés de vasières au niveau des zones d'embouchure. Des fonds durs existent et sont constitués de larges bandes de plaques rocheuses continues ou discontinues à des profondeurs de 50 mètres.

L'hydroclimat de la Casamance maritime est caractérisé par une saison froide de janvier à avril, une saison chaude de juillet à octobre et deux saisons de transition entre mai-juin et novembre-décembre (Chabanne, 1987 in Reber, 1983). La saison froide s'installe à l'arrivée des alizés sur le frange côtière, la saison chaude à leur chute brutale à leur passage au niveau de la zone intertropicale de convergences. Quant aux saisons de transition, elles apparaissent avec l'influence des eaux tropicales et la chute des alizés. Les dates d'apparition de ces trois saisons sont variables suivant l'installation plus ou moins tardive du régime des alizés d'une année à une autre. Cette situation est observée sur tout le littoral sénégalais. Les alizés sont à l'origine d'une importante production primaire et des fluctuations saisonnières et interannuelles de celle-ci. L'existence de courants marins entraîne une accumulation de cette biomasse dans les zones côtières peu profondes. Au niveau des zones d'estuaires, cet enrichissement par l'effet des courants est doublé par les apports des fleuves.

La saison d'upwelling démarre vers février et dure jusqu'en juillet. Son intensité est maximale entre mars et avril. D'une année à une autre, l'intensité de ces saisons varient suivant l'importance des alizés.

La salinité est marquée en fin de saison chaude par une dessalure importante sensible jusqu'à 50 mètres sur les fonds de Roxo.

## 3. PRÉSENTATION DE LA PÊCHERIE

La sole est exploitée le long de la façade maritime de Casamance par les flottilles chalutière et crevettière basées à Dakar et par les pêcheurs artisans sur place à partir des principaux ports de pêche de la région en mer, Kafountine, Cap Skirring, Diembéreng et Bukot. La pêche artisanale produit l'essentiel de la production achetée par les usines locales (plus de 97 % de la production totale).

## 4. LA PÊCHE

### *4.1 Les saisons de pêche*

Actuellement, on distingue trois saisons de pêche :

- de la fin de l'hivernage en octobre au tout premier mois de la saison sèche en décembre. Cette période correspond à l'installation des pêcheurs migrants [1]
- entre février et mai
- en hivernage (de juin à octobre). Les pêcheurs formés par le Projet de Développement de la Pêche Artisanale Maritime en Casamance (PAMEZ) sont les premiers à essayer la pêche de la sole pendant cette saison. Cette opération fut un succés. Depuis, de nombreux migrants ne retournent plus chez eux pour les travaux des champs pendant la saison des pluies.Ils n'arrêtent de pêcher pour rentrer dans leur village d'origine qu'à l'approche de la fête musulmane de l'*Aïd El Fitr* (ou fête du mouton). La durée de cette pose est d'environ un mois. Au Nord Sénégal, il n'y a qu'une seule saison de pêche. Elle est située au mois de mai.

### *4.2 Les pirogues utilisees*

Les embarcations utilisées sont les pirogues sénégalaises de mer (fig. 2). Ces pirogues sont motorisées.

### *4.3 Les caractéristiques des équipages*

Les équipages des pirogues à sole sont formées de 4 à 5 pêcheurs, appartenant à la même famille (frères ou cousins) ou non (cas des pêcheurs autochtones diola utilisées au niveau des unités de pêches Lébou et Ouoloff au Cap Skirring).

### *4.4 Le filet dormant à sole*

En Casamance, le filet dormant à sole est formé de plusieurs nappes de filet (30 et plus), de mailles différentes. Le nombre et la longueur de celles-ci varient suivant les communautés de pêcheurs et les possibilités financières des unités.

Les nappes de filet ont des longueurs qui vont de 3 à 12 m. Leur hauteur de chute est d'environ 1,5 m, leurs mailles sont de 40, 46 et 50 mm. Un filet est constitué de nappes de mailles différentes.

Jusqu'à une date récente en 1988, la campagne de pêche se déroulait essentiellement en saison sèche d'octobre à mai-juin avec l'installation des pêcheurs migrants venus du Nord Sénégal. De nos jours, elle s'étend sur toute l'année. La pêche de saison sèche est toutefois de loin la plus importante (c'est la période pendant laquelle il y a le plus grand nombre de pêcheurs).

### *4.5 Les marées*

Les pêcheurs de sole sortent le matin très tôt (entre 3 et 5 h) récupérer leurs prises. Les filets sont laissés en mer en début de campagne et sont visités tous les jours. Lorsqu'ils sont déchirés, les nappes correspondantes aux parties abîmées sont retirées pour être ramendées et remplacées.

Le filet est déplacé chaque fois que le rendement baisse.

La durée de pêche du filet dormant à sole est d'environ 24 heures, rarement au delà, 48 à 72 heures. Cette dernière situation est observée pour certaines unités de pêche du Cap Skirring en temps normal (les pirogues glacières), à Kafountine en période de mauvais temps (période de mer agitée : entre décembre et mars). Les prises (poisson pourri) sont alors transformées en produit semi fini : "guedj".

1. Ces pêcheurs constituent la principale composante de la population de pêcheurs en mer (plus de 90 % de l'effectif total d'après les différents recensements du service des pêches DOPM).

*4.6 Les prises*

Elles sont constituées principalement d'une seule espèce de Cynoglosses (*Cynoglossus monodi* : plus de 95 % des captures de soles), de mâchoirons, d'otolithes, d'ethmaloses, de plexiglasses... Les captures du second groupe constituées pour la plupart de juvéniles de mâchoirons, de pomadasys, d'otolithes bobo (*Pseudotolithus elongatus*) représentent une part importante des débarquements de la pêcherie (entre 40 et 80 % de la pêche suivant les saisons). Les adultes de ces poissons sont les cibles d'autres pêcheries (pêcherie des filets à gros poissons).

A Kafountine, les maximums de prises de sole sont observés entre février et mars et en octobre (fig. 3).

Pour l'ensemble de la pêche dans la région, les statistiques de la Direction de l'Océanographie et des Pêches Maritimes (DOPM) indiquent des captures de l'ordre de 165 tonnes en 1985 et 810 tonnes en 1990.

*4.7 L'effort*

La DOPM qui a la prérogative de la collecte des statistiques de pêche n'estime que l'effort potentiel, l'activité de pêche et sa répartition spatio-temporelle. Pour ce qui concerne l'effort potentiel, au niveau des engins de pêche les données sont relevées par type de pêche, filet maillant dérivant, filet dormant sans distinction des espèces cibles. Pour donc apprécier l'évolution de l'effort de pêche filet dormant à sole de ces dernières années, on utilisera les données du CRODT de 1985 et 1990 où cette distinction existe. Pour illuster cette augmentation, on peut citer le cas de Kafountine et du Cap Skirring où le nombre de filets à sole est passé de 695 à 1585 et de 429 à 3602 entre 1985 et 1992.

A Kafountine, le maximum de sortie est observé entre février et mars et en octobre (fig. 4).

*4.8 Les rendements*

Dans le principal port de débarquement de la sole, Kafountine, les rendements les plus importants sur deux périodes : entre janvier et avril et entre octobre et novembre (fig. 5). Ces périodes d'abondance correspondent à la saison de transition et à la saison froide.

Dans le sud au niveau du Cap Skirring, les PUE maximales de sole (55 et 41 kg) sont observées en juin et juillet pendant les tous premiers mois de la saison des pluies. Une baisse progressive des PUE s'installe ensuite jusqu'au début de la saison froide en janvier. L'augmentation des PUE débute durant la saison froide (de février à avril) (fig. 6 ; tabl. 1).

Au niveau de l'effort, il est intéressant de noter sa diminution synchrone avec l'augmentation des PUE à l'exception du mois de février.

Enfin à titre de comparaison, on peut noter que les PUE maximales de cette espèce dans ses principaux ports de pêche du Nord Sénégal, Saint Louis et Kayar sont plus importantes, 50 et 80 kg respectivement pour le premier et le second en 1985 (Laloe & Samba, 1990).

## 5. LES POTENTIALITÉS

Le potentiel de la sole pêchée par la pêcherie artisanale n'est pas connue mais au vue des résultats de la pêche il serait important. Partant des données d'exploitation de ces dernières années, le minimum de ce potentiel est évalué à 750 tonnes en 1991 (production totale de cette année).

## 6. LA COMMERCIALISATION DE LA SOLE

La sole pêchée en Casamance est achetée sur place par les usines locales. Elle est vendue pour l'essentiel (plus de 95 % de la production) sur le marché étranger, en France, en Allemagne... et constitue une source de devises pour l'économie nationale. La part de la production absorbée par le marché local est achetée par les hôtels de la région et les particuliers (les restaurateurs surtout).

En 1988, ces usines se procuraient la sole directement auprès des pêcheurs à qui ils avaient prêté du matériel de pêche et des fonds de campagne. Les montants équivalents au matériel prêté ainsi que les sommes d'argent données sous forme d'avance de campagne étaient récupérés sur la vente des produits suivant un taux fixé en commun accord entre 5 et 10 % sur le prix de vente du kilo de sole. Mais très vite, les usiniers allaient dénoncer le manque de sérieux de nombreux pêcheurs qui n'amènent pas l'intégralité de leurs prises à l'usine et quittaient même souvent clandestinement la région pour d'autres lieux de pêche.

Devant une telle situation, les usiniers allaient réagir en développant une autre stratégie limitant le risque de non remboursement de leur prêt. Pour cela ils allaient nouer des relations de confiance avec des mareyeurs installés pour leur propre compte sur les plages de débarquement. A ces derniers, ils apportent gratuitement la glace et font des prêts de campagne.

Les mareyeurs travaillent avec des groupes de pêcheurs (10 à 50 pêcheurs) auxquels ils fournissent gratuitement la glace et consentent des prêts d'équipement en matériel de pêche et en espèces pour leur permettre de faire face aux dépenses de campagne. Le matériel et l'argent prêtés sont récupérés sur le prix de vente du kilo de sole comme ceci se faisait avec les usiniers. Les pêcheurs doivent leur vendent en retour leur production de sole.

La production collectée par les mareyeurs travaillant en contrat avec les usines est ramassée chaque jour par les camions frigorifiques affrétés par l'usine au niveau des principaux ports de débarquement de la sole.

Depuis plus de trois ans aujourd'hui les pêcheurs de sole en mer en Casamance vendent à ces mareyeurs la production de leur pêche concernant cette ressource. Une infime partie moins de 2 % de la production va à la transformation artisanale (il s'agit des débarquements de la sole non frais).

## 7. CONCLUSION

Le filet dormant est le seul engin de pêche utilisé principalement pour la capture de la sole au niveau de la pêcherie artisanale maritime casamançaise. Ses captures sont très diversifiées et relativement abondantes avec espèces dominantes les mâchoirons et les otolithes. La proportion de ces dernières espèces dans les débarquements est plus importante dans les captures du filet dormant à sole en saison chaude entre mars et juin.

Les rendements de saison de pluie sont importants mais du fait que l'effort de pêche est en diminution pendant cette période avec le retour de la plupart des pêcheurs migrants dans leur village d'origine, il est difficile de lier cette situation à une abondance de la ressource pendant cette période. Des campagnes d'évaluation sont nécessaires à ce stade ceci d'autant plus que le potentiel de sole (*Cynoglossus sp.*) connu ne concerne que les espèces capturées au niveau de la pêche industrielle. Le potentiel de la sole exploitée par la pêche artisanale (*C. monodi*) n'est pas connue.

Au niveau de la commercialisation, le rôle de banquier joué par le mareyeur auprès des pêcheurs et de l'usinier auprès des mareyeurs est à souligner. L'efficacité de l'approvisionnement des usines de Ziguinchor en sole tient à la solidité de ces relations.

# Skipjack Pole and Line Fishing in East Indonesia

**James Kevin McElroy[a] and Jacobus C.B. Uktolseja[b]**

[a]Landell Mills Management Consultants, Jl. Plaju 6 - Jakarta Pusat 10230, Indonesia

[b]Research Institute for Marine Fisheries, Jl. Muara Baru Ujung Complex Pelabuhan Baru Samudera, Jakarta-Utara 14440, Indonesia

ABSTRACT

*Given the geographic spread of existing skipjack pole and linefishing bases in east Indonesia, the paper analyses the relative importance of several interactive factors on pole and line vessel catch performance, including the effects of vessel size, horse power and age ; crew size and skill ; availability and abundance of bait ; season ; weather ; use of Fish Aggregating Devices (FADs) ; location of the fishing ground, and 'fleet congestion'. Partly from this comparative analysis, it is postulated that the resident stock of skipjack in this area is supplemented by large seasonal migrations from the western Pacific stock. As the bulk of this immigration must pass through the waters north of Irian Jaya, this region must offer some of the best fishing opportunities, and hence will have the highest priority for the future development of skipjack pole and line bases in Indonesia.*

## 1. PRODUCTION

### *1.1 National Production*

The Indonesian skipjack pole and line industry operates only in east Indonesia, and in 1989 accounted for about 63 % (71,400 mt) of the Indonesian skipjack catch (113,850 mt). About 80 % of the total skipjack catch is taken in east Indonesia.

This method of fishing has shown a dramatic increase in the number of vessels and production in recent years (Table 1).

### *1.2 Breakdown by Provinces*

Between 1980-1989, skipjack pole and line fishing in east Indonesia accounted for 92 % of the growth in the skipjack catch in that region ; and three quarters of the increased skipjack catch in the country as a whole (Table 2).

Table 2 also shows the relative importance of the different fishing regions in east Indonesia,as subdivided by McElroy (1989). Almost all the skipjack catch is taken by the northern group comprising Irian Jaya, Maluccu and Sulawesi ; only 8 % is taken in the southern group provinces of Bali, West Nusa Tenggara (NTB), East Nusa Tenggara (NTT) and East Timor (TT).

It is postulated here that the 'resident' stock of skipjack in east Indonesia is supplemented periodically by large migrations from the western Pacific Ocean stock, which occurs in large concentrations north of Papua New Guinea for most of the year (Marcille et al, 1984 ; FFA, unpublished catch/location data, and SPC, 1991). Some supporting evidence for this hypothesis is presented here, based primarily upon an analysis of the pole and line fleet's fishing performance at six strategic locations in east Indonesia (see Figure 1 and Table 3).

There are eight principal pole and line fishing bases in east Indonesia. These are :

- in the northern provinces : *Sorong* (11,500 tons) and *Biak* (2,500 tons) in Irian Jaya ; *Penambuan* (6,200 tons), *Ambon* (2,000 tons) and *Ternate* (2,000 tons) in Maluku ; *Bitung* (2,500 tons) and *Kendari* (5,700 tons) in Sulawesi.

- in the southern provinces : *Maumere* (2,000 tons) in East Nusa Tenggara (The tonnages in brackets represent actual or estimated skipjack landings in 1990).

A number of factors affect the performance of any skipjack pole and line fleet. The principle factors are vessel size (gt), horse power (Hp) and age ; crew size and skill ; availability and abundance of bait ; season ; weather ; use of Fish Aggregating Devices (FADs) ; location of the fishing ground ; and 'fleet congestion'. These factors are all interrelated, some being more important than others under specific circumstances.

Table 3 summarizes available data on several of these factors for six locations in east Indonesia. Some of the most important relationships are identified below.

## 2. VESSEL SIZE, HORSE POWER, CREW SIZE AND SKILL

### *2.1 7.5gt and 15 gt*

Three vessel sizes are shown in Table 3, namely 7.5 gt (30-45 Hp, 8-10 crew), 15 gt (80-105 Hp, 12-15 crew), 30 gt (160-240 Hp, 15-17 crew). As indicated, both the propulsion unit (Hp) and crew size increase with vessel size. Not surprisingly, therefore, so does the catch. At Penambuan, where both 7.5 gt and 15 gt vessels were in operation on FADs at the same fishing ground between March 1987 through March 1991, a 50 % increase in the average number of crew fishing from 9 to 13.5 led to a 71 % increase in catch/operating day, from 461 kg/d to 790 kg/d.

The larger vessels used somewhat more bait per kg of skipjack landed, the relative values being 28.4 kg fish per bait bucket for the 7.5 gt vessels against 23.9 kg fish per bait bucket for the 15 gt vessels. In taking the greater catch, the larger vessels may have carried out more 'open water' fishing, which tends to absorb a greater amount of bait per kg of fish landed.

### *2.2 15 gt and 30 gt*

An increase in catch/operating day was less obvious between these two size groups. Unfortunately, none of the six locations operated both vessel sizes.

Comparing 15 gt and 30 gt vessels operating *without FADs*, as shown below, at Maumere (15 gt), Ambon, Bitung and Sorong (all 30 gt), the catch per effective fishing day, which is defined as an operating day with non-zero catch, was similar for these different vessel sizes, suggesting other factors probably had a greater influence on catch than the factors of vessel size, Hp and crew size.

| | Vessel Size (gt) | Catch Kg | Coefficient of variation % |
|---|---|---|---|
| Maumere | 15 | 792 | 30.7 |
| Ambon | 30 | 730 | 26.7 |
| Bitung | 30 | 808 | 34.7 |
| Sorong | 30 | 890* | 16.8** |

Source: Table 3
Notes: Coefficient of monthly variation in catch.

* estimated catch/effective fishing day from catch/operationnal day data for Bitung.
** applies to catch/operationnal day data.

Specifically, the performance of the Maumere 15 gt vessels between 1983-1987 was on a par with the larger vessels (30 gt) at Ambon and Bitung, all of which suffered from problems of bait availability, but was some 12 % below the larger vessels (30 gt) at Sorong, where bait availability was generally not a problem. However, the high coefficient of variability (C.V.) at Maumere is considered to be more a function of the highly seasonal nature of that fishery rather than strictly a result of a shortage of bait during the period in question.

There is a similar lack of any clear difference for the situation *with FADs*, again most likely because of the swamping of this influence by other factors.

| | Vessel Size (gt) | | Catch Kg | Coefficient of variation % | No. of operationnal days no bait available % | Catch/bucket (kg/B) |
|---|---|---|---|---|---|---|
| Penambuan | 15 | EFD | 790 | 27.6 | | 23.9 |
| Kendari | 30 | EFD | 1,118 | 19.3 | | |
| Bitung | 30 | EFD | 1,004 | | | |
| | | OD | 868 | 15.4 | 12 | 18.9 |
| Sorong | 30 | EFD* | 1,270* | | | |
| | | OD | 1,096 | 11.7 | | 26.8 |

Source: Table 3

EFD : Effective Fishing Day (operational day with non-zero catch)
OD : Operational Day
* estimated from ratio of catch/OD to catch/EFD data for Bitung

It is possible the differences that do exist between Penambuan and Kendari (both use 15 gt vessels) reflect more the skill of the crew, as Penambuan fishermen are generally less experienced as theirs is a relatively new fishery.

## 3. AVAILABILITY/ABUNDANCE OF BAIT AND THE IMPACT OF FADS

There is sufficient numerical evidence to compare this influence only between 30 gt vessels operating 'open water' fishing at Ambon and Bitung ; and at Bitung, between the situation *before* and *after* the introduction of FADs.

### *3.1 Availability/Relative Abundance of Bait*

As Table 3 shows, the proportion of operational days when no bait was available was twice as high (34 %) at Ambon compared to Bitung (17 %), despite the appreciably lower variability in the size of the average catch between months at Ambon. The catch/operating day is one third lower at Ambon (being only 68 % of the catch/OD at Bitung), which may partly be explained by the higher number of operational days at Ambon (19.6 days/month) compared to Bitung (16.0 days/month). Assuming that availability and abundance of bait changes over the course of a lunar cycle in a predictable way, the additional 3.6 operational days/month will generally be during the poor bait period, when catches will presumably be lower. This is best illustrated by comparing the difference in average catch /effective fishing day, when

at least some fish was caught, at both locations. Here, the catch/operational day in Bitung is only marginally higher (10 %) over Ambon, viz. 808 kg compared to 730 kg. As the number of effective fishing days in Bitung is also higher than in Ambon, 13.5 days against 12.3 days, it would appear that, *ceteris paribus,* Bitung benefits from having a better bait supply compared to Ambon with yields of 16.9 kgs of fish per bucket and 68 kgs per bucket respectively. This finding is also supported by anecdotal evidence.

This comparison is between two areas operating 'open water' fishing.

### *3.2 Abundance of Bait and the Effect of FADs*

The comparison is drawn here between the catch efficiency of 30 gt vessels *before* and *after* the introduction of FADs at Bitung.

While the number of operational days/month is the same, at 16, the number of effective fishing days is increased marginally using FADs, being 13.8 days with FADs against 13.5 days without. More striking, perhaps, is the increase in the weight of fish landed per bucket of bait ; with FADs, this is 18.9 kgs, without FADs, 16.9 kgs. Also the number of operational days when no bait was available was higher before the introduction of FADs, 17 % of the operational days against 12 % after their introduction. This may simply reflect more the need for a lower weight of bait to justify economically a trip to the fishing grounds with FAD compared to the weight required without FAD. Hence the proportion of 'insufficient bait' days as opposed to 'no bait' days is probably reduced using FADs.

### *3.3 The Effect of FADs*

Given that the above differences (item 3.2) are relatively small at Bitung, we can compare reasonably directly the catch efficiency of 30 gt vessels *before* and *after* the introduction of FADs at Bitung.

| | Without FAD | | | With FAD | | |
|---|---|---|---|---|---|---|
| | Average/month (days) | Average catch/ operating day (kg) | C.V. % | Average/month (days) | Average catch/ operating day (kg) | C.V. % |
| Operational Days | 16.0 | 673 | 34.7 | 16.0 | 868 | 15.4 |
| Effective Days Fishing | 13.5 | 808 | | 13.8 | 1,004 | |

Source : Table 3
Note : C.V. Coefficient of variation in average monthly catch.

The two outstanding features, resulting from the introduction of FADS as highlighted in the table above, are (a) the increase in catch/day of between 24 % to 29 % on operational days and effective fishing days respectively, and (b) the reduction in average catch size variability between months by more than half (15.4 compared to 34.7).

The reduction in 'month-to-month' variability in average catch size has another important feature. Relative to the average catch level *without FADs*, the number of 'above average fishing' months is higher *with FADs, than without FADs.* By way of example, at one location the number of significantly 'above average' months rose from 4 to 7 after FADs were introduced (Figure 2). This has important implications on the economic viability of the P & L fleet and also of shore-based processing facilities.

## 4. OTHER FACTORS

### *4.1 Vessel Size and Weather*

The number of operational days per month tends to be higher the larger and more seaworthy the vessel, although the differences at more protected locations may not be very large (Table 3).

*4.2 Vessel Age and Crew Experience*

In principle, the longer a vessel and crew are together the higher tends to be the catch, at least during the first few years of a vessel's economic life. As it ages, the average number of operational days/month of a fishing vessel tends to decrease, although the catch/operational day may remain unchanged. Wooden pole and line vessels have an economic life of between 7-15 years in Indonesia. The effect of vessel and fleet age on percentage operational days and average catch performance is shown in Figure 3 for the State Fishing Company PT. Usaha Mina, at Sorong.

*4.3 Bait Availability, Geographic Location and Fleet Congestion*

In the case of pole and line fishing congestion' can occur as a result both of (a) a shortage of bait/vessel or (b) too much fishing power in one area. The effect may be general, seasonal or limited to a certain period of each month.

Good virgin fishing areas, which yield 'above average catch' rates, attract more vessels. Over time, this tends to cause a decline in average catch/vessel.

Because of a number of natural factors, some grounds tend to have a higher productivity (refer Table 3 and Figure 2). In the waters of east Indonesia, this is a notable feature. In the eastern part of the northern group, i.e. around Sorong, Irian Jaya, average catch per unit effort (C.P.U.E.) is high with a low seasonal variability. Moving westward but still in the northern sector of east Indonesia, there is a marked decline in average catch and increase in seasonal variability. To the south and west of Irian Jaya, i.e. in the Flores and Banda Seas, the average CPUE also declines and seasonal variability increases. This result would appear to corroborate the hypothesis that the skipjack resources of the northern waters of east Indonesia are supplemented seasonally, at least in part, with fish from the western Pacific skipjack stock.

This finding has important implications for the development of skipjack fishing bases (whether pole and line or purse seine) within east Indonesia. Indeed, it is a central plank of recent proposals for fishing port and processing industry development within east Indonesia.

## 5. CONCLUSIONS

Because of the geographic spread of existing skipjack pole and line fishing bases in east Indonesia, it has been possible to analyse here several important interactive factors on pole and line vessel catch performance.

(i) The significance of FADs in (a) substantially increasing the average skipjack catch/vessel and (b) reducing seasonal variability of the average size of the catch/vessel has been demonstrated here. FADs provide a useful method to increase vessel productivity and reduce vessel operating costs, thereby increasing disproportionately the economic performance of the pole and line vessel.

(ii) The central importance of bait to skipjack pole and line fishing is well known and has again been demonstrated here. FADs can help to increase catch levels for a given amount of bait, thereby enabling a fishery where bait is a limi tation to increase its total catch.

(iii) The skipjack resource of east Indonesia is in part derived from the western Pacific Ocean stock through migration. As the bulk of the fish entering the east Indonesian ar- chipelago first must pass through the waters north of Irian Jaya, this region must offer some of the best fishing opportunities, and hence will have the highest priority for the development of skipjack pole and line and purse seine bases. After Irian Jaya, in importance, comes Maluccu, and then Sulawesi. In the southern waters of east Indonesia, there is a highly seasonal skipjack fishery. As such, it may have the lowest priority for developing a dedicated skipjack pole and line fishery. Its greatest potential for development may be through a seasonal skipjack pole and line fleet or the use of the same vessels for multi-purpose fishing operations such as longlining or gill net fishing during the low season for skipjack pole and line fishing.

ABSTRACT

*In order to optimize fish production factors and realize viable production process, a sample of sea bass, sea bream, eel and trout farms has been carried out during 1991.*

*Questionnaires have been sent to farmers or presented direcly to them by interviewers ; questions relate to wide-ranging information on ownership status, cultural background, decision making process, role of collaboration, regular and part-time labour, investment aspects, support and marketing policies.*

*The survey focuses on the interactions between the cultural matrix and the background, to determine wheter they, together with the competitive environment, influence the managerial behaviour of the entrepreneur. In order to identify similar groups of farms and relating behaviours the cluster analysis has been applied to the matrix of global variables.*

*As far as the managerial aspect is concerned, two points have been focused on : the level of internal centralization of the decision-making process and the existence of a management planning logic. Results showed a low level of delegation in the decision-making process and only a number of entrepreneurs were profit oriented, with a management planning logic.*

*Generally speaking, the entrepreneur is well educated, experienced, focuses on the objectives of profits and investments and is aware of foreign competition in the sector. However, the existence of occasional entrepreneurs whose only aim is profit, has been evidenced ; they are not concerned with problems related to the market, and only consider investments in aquaculture as a means of making money.*

* The authors all contributed to this report, but in particular, during the preparation of the draft, Carla Iandoli wrote paragraph 3, Eugenio Alaio paragraph 2 and 4.2 with the collaboration of Rosario Bianco, R.Bianco paragraph 4, and Giuseppe Vito paragraph 1. Conclusions were drawn from the common work of all authors.

*As far as producer organizations are concerned, great concern is shown on the subject in the trout sector, due to a long-lasting tradition ; on the contrary, farmers involved in the eurhialin species sector lack a sense of collaboration, even though they may realize that it could help them solve most problems related to the aquaculture sector.*

## 1. INTRODUCTION

Aquaculture in Italy is a growing sector, which has recorded high rates of development in the last few years. At present, this sector consists of about 1,300 fish farms and 60,000 hectares of lagoons, the production of which in 1991 reached 161,000 tons for a value of 417 billion liras. The strong dynamic of development of the activities of this sector has aroused the interest of researchers who, according to different lines of approach and interests, have investigated the production sector with the view of determining the characteristic qualities of the sector. If we consider the approach from an economic and corporate point of view, in this historic period of development, aquaculture activities in Italy can be investigated from two standpoints.

As far as the first aspect is concerned, we deem it interesting to determine the structural characteristics of the sector, the dynamics of the economic factors, the evolution of the natimortality of firms, the conditions of competition, the role and the importance of the research activity on company performances, the level of foreign trade, the characteristics of the demand for services by firms and all that is necessary to define the industry specific features of this productive activity.

The second aspect, more specific and limited and which offers particular opportunities of interest for the company's economist in the approach to analysis, is connected with the thorough investigation of the determining factors of entrepreneurial ability in the sector. The concomitance of the development of a « new » activity in a « new » settlement area, offers researchers the opportunity to make out the determining factors of the phenomenon according to two « vectors », which influence the characteristics of entrepreneurial ability : the economic characteristic qualities of the sector and the socioeconomic characteristics of the areas of location.

By conforming to this line of approach in the present report, we have first analyzed and described the structural characteristics of the fish farms which make up the sector. The productive activities of the sector appear extremely different in the technologies adopted, in the species raised, as well as in management and production plans. Another difference concerns the level of capital intensity for the setting up and management of fish farms, the level of which varies according to the production and organization models adopted, of which heterogenous productivity rates are the counterpart.

While the management of the activities connected with « valli », lagoons and ponds requires limited capital, the facilities for intensive fish-farming are characterized by capital intensity. Such characteristics seem to be of great importance in a moment in which the industrial policies of the sector are necessarily oriented to the realization of favourable conditions for the start-up of fish farms.

The study has then analyzed the relationship between the training processes of entrepreneurs and some characteristic qualities of their managerial ability, in order to determine the similarities and differences present in the entrepreneurial « culture » of the sector. Such knowledge, in this case too, becomes instrumental with respect to the possible public actions of intervention especially in relation to the characteristics of the services offered to fish farms. The scientific literature has widely illustrated the evolutionary characteristics that the contents of the firms services have to take on in order to optimize the growth of the activities of a specific sector/area.

By approaching this analysis plan from the two above-mentioned standpoints, we think we have offered an initial contribution to the description of economic and corporate characteristic qualities of the aquaculture sector, which is by no means complete but offers incentives and opportunities for further checks, developments and critical investigation.

### *2. Materials and Methods*

The survey was carried out by interviewing those who are engaged in the management of a fish farm for a sample of fish farms operating in the sector of mussel-farming, trout-farming and the farming of euryhaline species.

The output of fish farms amounts to 63,000 tons, equal to about 40% of the national output (161,000 tons in 1991). The interviewees were asked a series of questions the purpose of which was to gather elementary variables for the working out of global, yet qualitative indicators, which could allow interviewers to sketch the profile of the entrepreneur of the sector in order to determine the origin of the interviewees, their background, the development of the fish farm and the influence of the strategies adopted. The data thus obtained were carefully analysed in order to free the answers obtained from the inconsistencies which may derive from the intention of the interviewees to give an idea of themselves different from the real one. Control questions were asked and more significant answers were obtained by cross-checking elementary answers. Cluster analysis was then applied to the matrices of global variables in order to identify groups of fish farms which met the same requirements for belonging to the group and determine standard behaviour and trends of the universe surveyed.

In relation to the variables representative of training and cultural values, the analysis of training processes was carried out by separating the processes connected with learning by instruction from the processes of empirical nature, that is to say based on learning by doing. This analysis was made more precise through the pursuit of any possible direct relationship between activities carried out and training path.

## 3. SECTOR'S STRUCTURE AND DYNAMICS

The aquaculture sector in Italy is deeply differentiated and characterized by the influence of environmental, technological, organizational and managemental variables.

The most active section, characterized by a heavier technological and managemental impact, is that of brackish waters aquaculture in which sea bass, sea bream, mullet, eel and mussel are cultured.

The Italian output for 1991 amounted to about 161,000 tons, distributed as follows : 66% of molluscs, 23.4% of trout, 3.3% of euryhaline species and 2.2% of eel ; it is sold especially on the home market, and in particular 52% on the national market and 27% on the local market ; only 21% of the total output is exported. The value of the production (Lira of 1991) is equal to 417,5 billion liras ; such data point out the prevalence of low-unit-value cultures such as mussels and eel. However the most profitable species, more appreciated by the Italian consumer, are euryhaline species.

1285 aquaculture facilities were registered for assessment in 1990, with a regional distribution characterized by a high concentration in Veneto (about 25% out of the total) and in Emilia-Romagna (about 16% out of the total).

The growth trend of the Italian aquaculture sector is the result of two major phenomena : on the one hand, the new diet which leads to an average demand per capita equal to 15 kg of fish, which is still far from reaching European averages, and on the other the difficulties connected with fisheries and the excessive exploitation of the sea. If we connect these phenomena with the preference of consumers for fresh food products, we can clearly see the need to concentrate on aquaculture and on the processing industry of fresh food products connected with it. Indeed, we have not made good use of the opportunities and the supply of fish products from foreign markets amount to almost 50% of home consumption among fresh, quick-frozen and deep-frozen products in 1989. The situation relating to foreign trade did not improve until 1991, but the data of the first six months of 1992 seem to show a trend in the opposite direction compared to the same data of 1991.

In spite of the difficulties related to setting up the facilities, workers do not have specialized functions and there are gaps in the technical knowledge of employees. 55% of the personnel are hired, but considerable percentages of positions are held by the families and partners.

We notice an insufficient presence of phenomena of vertical integration, either of the backward type, represented by the possibility of carrying out the activity of reproduction as well as of growing-out, or of the forward type towards the distribution phases. As far as the last phenomenon pointed out is concerned, it comes out that only 9% of the fish farms has their own distribution centre, whereas the largest portion of trade is controlled by wholesalers (52%), followed by fish markets (24%), retailers (3%) and game-fishing (2%). The remaining 18% are represented by other forms of marketing.

The description of the sector given above is characteristic of growing sectors (except for mussel-farming), characterized by the continuous pursuit of a proper economic/financial balance on the one hand and a production/distribution balance on the other.

As far as short-term strategies are concerned, we see emerging primary objectives of facilities' expansion, aiming at economies of scale, minimization of cost and improvement of the quality of the product.

In the last five years, entrepreneurs have increased their productive capacity in order to minimize costs, purchased equipment and hatcheries. In this period only 4% of the entrepreneurs did not invest.

The financing sources used are mainly self-financing (44%), public funds (23%), loans and soft loans (20% and 12% respectively).

In support of the requirements for the economic, financial and managemental start-up of the sector's operators, the European Economic Community contributed by financing in Italy, according to Reg. 2908/83, in the period 1983/86, 38 facilities for a total value of 12,333,967 ECU and another 41 facilities, according to the subsequent Reg. 4028/86, in the period 1987/90 for a value of 21,460,990 ECU.

## 4. ENTREPRENEURIAL PROBLEMS

### *4.1. Introductory remarks*

The study of the entrepreneurial characteristics of the aquaculture sector offers opportunities of analysis for the main lines of investigation of the debate. In particular, there is a potential connection with the line of analysis which studies the connections between the characteristics of the economic environment of settlement and the start-up dynamics of fish farms, in order to determine the « objective » factors which affect the growth of successful fish farms, with the purpose of identifying the determining factors of development and growth of entrepreneurial ability. In relation to certain lines of investigation, national or international and/or within or among sectors, and with a firmly-established quantitative approach, such line of analysis breaks down into a series of lines of investigation connected with the identification of the main difficulties encountered by the new fish farms, with conditions of optimal balance among internal resources and environmental opportunities (Norman 1979, Coda 1984) and with the analysis of motivation and incentive values for personnel through an approach of organizational matrix [1].

In the panorama of the specific literature, in addition to these areas of investigation, there has been an increase in the analysis efforts of the « cultural » line, which analyzes the role of corporate

culture, intended as the whole of guidelines, in the company's dynamics (Gagliardi 1986, Bosche 1984, Thevenet 1984), trying to connect its importance to the company's performances (Lemaitre 1984, Kotter, Heskett 1992), even investigating the relationship existing between vocational-training path and typologies of entrepreneurial ability (Calvelli 1990).

However, the possibility of applying the last line of analysis to the aquaculture sector turns out to be limited by the fact that this activity has only recently appeared, thus preventing the sector from acquiring its own cultural features.

At present two prevailing dynamics seem to emerge from the paths which led the entrepreneurs of the sector to undertake the activity. The first path comprises those who have undertaken the activity by virtue of the « technical » skills they possess and consider suitable for determining favourable conditions for their activities. In particular, this group consists of the operators who previously worked as researchers or fishermen, or carried out other fishing activities. On the other hand, the second path seems to apply to those who possess real estate, plots of land and/or « assets » which can be used to make profits in the aquaculture sector.

1. « Studies on entrepreneurship in Italy » seems to be representative of the different lines of systematization and investigation of the theme ; published by Lorenzoni and Zanoni (1988) it contains recent systematized studies coming from different matrices and therefore aimed at investigating different aspects of the theme. In particular, it includes contributions of social matrix (Dalla Chiesa) and of statistical-quantitative matrix (Brasini, Tassinari), while in the group of economic-corporate approach, it can be seen lines of environmental analysis (Dubini, Schillaci), of the analysis of the determining factors of the entrepreneurial phenomenon (Colombo, Lorenzoni) and of the analysis of the mechanisms of diffusion (Del Monte). Other elements of investigation are the dimensional variable, which leads to investigate characteristic qualities connected with the small-scale firm (Boldizzoni), and the territorial/functional/sectorial components (Stampacchia, Lorenzini and Fabbriciani, Carlesi, Manaresi and Zanoni).

Such evidence points out then the possibility of going on with the research with the objective of constantly monitoring in the next future the performances of fish farms characterized by the presence of entrepreneurs coming from the two groups, established in order to evaluate and measure the dynamics of the relationship between the specific preparation of the entrepreneur and the success of his enterprise. Furthermore, in perspective, we see the possibility of studying the possible birth and growth of a « homogeneous » entrepreneurial culture within the sector, which can be evaluated through the formation of « myths » (Calvelli 1990) and common values. In particular, it seems possible that the two geneses of the current distinctive skills of entrepreneurs, determine new and common characteristics or the predominance of an approach over the other ; moreover, new connections could emerge between the entrepreneurial activity and the economic environment capable of affecting the prevailing entrepreneurial culture.

*4.2. The Results of the Survey*

As for the objective of specifically identifying whether vocational training, either empirical or strictly didactic, is somehow correlated with the activity carried out or it is completely independent of it, the application of the analysis of the main components to the identifiers of vocational training (education, specialization, previous experiences, years of practice of the current activity, reasons for becoming an entrepreneur, father's job, place in which the interviewee lives, opportunities of refresher courses, opportunities of trips) has made it possible to identify two basic clusters, on the basis of two components which together account for 40% of the total variance of the sample observed (Fig.1).

The first cluster includes the experts of the sector (20%) whose characteristics are a wide specific experience in the section, a degree in scientific disciplines (48%), followed by a postgraduate specialization in 45% of the cases ; the previous work experiences, when present, have been acquired in the same sector (21%), whereas in 39% of the cases it is the first job. The second cluster comprises the self-made men represented by 27% of the subjects who are former employees of the same fish farm or of rival fish farms, and in some cases sons of fishermen (6%) that, by virtue of a new choice (28%) or to go on with the family's activity (18%), have decided to work on their own.

The self-made man is a person who acquires his training day by day, that is he acquires his skills from his daily work and from the unconscious application of heuristic to a high technical-scientific content activity. The level of instruction is however influenced by the age of the subject, due to the fact that the degree of school attendance has considerably increased. 30% of the subjects interviewed has on the average 4 years of experience in the sector, whereas 24% has been working for more than 20 years : 91% is aged between 25 and 56. The activity carried out by the father has only a minimum influence on the cultural values, only 30% comes from a family of entrepreneurs, that in 12% of the cases carries out an activity completely different from the activity of the son.

The close examination of the cultural values has been carried out by analyzing the factors considered hindrances to the development of the activity and to the propensity to forms of cooperation. With reference to the last aspect, the opinion of entrepreneurs on the prospects of cooperation existing in the sector has been correlated with the knowledge the subjects possess of the forms of cooperation between firms (relations among firms and trade unions, real evaluation of motives which are the basis for belonging to a certain trade union, knowledge of the other forms of cooperation) (Fig.2).

The main components which are the most representative ones account for 54% of the total variance and include the references to the cooperation factor and the emotional and motivational factors which have led the subjects to choose this activity. The basic motive is profit, and there is frequently an excessive elevation of the goodness of one's own choices in terms of production which stands out among the others. The clusters identified include, respectively, 19% and 42% of the firms interviewed. The first cluster comprises the subjects who are clearly opposed to cooperation and that in substance refuse to transfer knowledge and experience to the other operators of the sector. The second cluster includes those who are in favour of cooperation but who do not pursue it, since they constantly tend to preserve their firm from external stimuli. This is to be attributed to the firmly-established tendency to mistrust the other operators and to the lack of distinctive skills capable of saving their competitive position.

In relation to the managerial behaviour, the size of the firms examined (only 12% have more than 30 employees, 45% has no more than 5) is unsuitable for a precise analysis of the factors which may identify the lack or presence of a managerial component ; we have then focused on the aspects relevant to the degree of centralization of the decision-making process and to the management control.

The level of delegation was put in relation with the tendency to spread information within the firm, considering it a good indication of the tendency to involve all the personnel in the decision-making process of the firm which can, within certain limits, increase management efficiency (Fig.3).

The duties delegated usually concern administration and production ; however, in 68% of the cases it is necessary to have the prior authorization of the top-level decision-makers. Such a form of delegation has been given a reduced weight with reference to the characteristics previously adopted as well as for the specificity of the duties delegated.

The clusters identified represent firms which have a low level of delegation and which are characterized by low employment, in which there is a high centralization of the productive functions and a limited propensity to changes, in consideration of the fact that the transfer of knowledge within the firm may damage the efficient behaviour. On the contrary, there are firms for which, even in the presence of a low level of delegation, there is the participation of men in favour of changes and interested in the changing corporate sociology and in the surrounding environment. The first group includes centralizers (33%), the second group innovators (18%), subjects with good managerial contents and in favour of innovations and changes, a tendency which is more in keeping with medium-scale and big firms. The main components used account for 45% of the total variance.

The management planning logic has been analyzed with reference to the adoption, within the firm, of any instrument of preventive analysis and concomitant or subsequent control. 82% of the firms declare that they carry out management control. The instruments used are budgets (18%), cost accounting (30%), production statistics (24%), asset and liability statements (3%), cash situation (15%).

The clusters identified are the following :

1.bigger labour-intensive firms with a large share of the market over the national territory, which use planning and control high-statistical-content instruments and cost accounting (45%) ;

2.firms operating on the local or regional market, run by a family with 3 to 5 employees on the average. The company's leadership is concentrated in the hands of one only person with low-level education ; advanced forecasting and control techniques are not used (30%) (Fig.4).

Obviously in every firm the entrepreneur and/or the manager (Schumpeter distinguished between the manager and the entrepreneur, but we can object that it is the manager that runs the firm, by holding a position connected with specific duties within the firm, but the manager can act in his capacity as entrepreneur, if we exclude that in a firm there must necessarily be a decision-making hierarchy among subjects employed to make decisions of vital importance) may affect, with their personalities and the decisions they make, the life of the firm itself. For this reason we decided to study how the behaviour of the decision-makers identified may affect the corporate strategies in progress and being advanced.

Two major components were correlated, representative respectively of the personalities which make it possible to identify the entrepreneur/manager as centralizer or decentralist and make remarks on the strategies. The two components account for 45% of the total variance (Fig.5).

The firms belong to a macroaggregate representative of the moderately decentralizing tendency of decision-making processes. Such aggregate, in turn, can break up into two subsets which differ in the strategies they pursue and for the level of the mentioned decentralization. We find strategies aiming at the extension of the corporate size and thus of the productive capacity with the objective of attaining technical and economic efficiency by involving all the personnel of the firm. They are typical strategies of investment, at least in the initial phase, which then translate into strategies of growth in the intermediate phase. On the other hand, there are firms with a greater centralization of the decision-making process in which they pursue technical and economic efficiency by the use of traditional techniques oriented to the optimization of plants and production processes, but not considering the motives of personnel and their possible innovative stimuli. Nevertheless, the type of strategy pursued and the results obtained depend on the external or internal ties of the firm.

The application of the cluster analysis by variables representative of internal/external ties (used and available technical assistance, important factors for the growth of the activity, profits, company control, initiatives of the public administration, factors boosting the development of the sector, relations with banks and insurance companies, cooperation) has focused attention on such limiting factors as : insufficiency of the bank credit, due to the high rate of return required by the firm as well as to the technical difficulties in distribution ; inadequacy of public contributions, which do not meet the real requirements of corporate management ; lack of a real and efficient consulting network for firms (which, although it is present, contributes to the rise in running costs) ; loose ties between scientific research and entrepreneurial world (which neither boosts nor contributes to the formation of micro industrial zones or pseudo industrial areas) (Fig.6).

The components employed in the analysis account for 40% of the total variance of the sample. The clusters identified represent, respectively, 52% of the firms projected into the real situation proposed, and 18% of the firms which have a rosier future for different reasons. They have a greater profitable capacity, they succeed in self-financing to a greater extent, they have better relations with the credit system. Ties, the cultural background of decision-making centres, and strategies affect the competitive position of the firms.

The combined analysis of the strategies in progress and the competitive position of firms yielded the following results. The prominent strategic objectives are the pursuit of the quality of the product, aimed at innovative success on the market, and the traditional pursuit of technical and economic efficiency.

Factors representative of the competitive position are the production trend chosen, the segments of the market in which the firm operates, the services offered and scheduled, investments (Fig.7).

Concerns are divided into two main groups. The first group (27%) includes the efficiency-oriented firms which work on the local or national markets, the objective of which is to increase their productive capacity (investment strategies), even by the optimization of intensive forms of production, which in substance do not offer any important service to the customers. The second group (10%) comprises the firms working also on foreign markets, but only to a limited extent (16%), oriented to the quality of the product and to the customer (punctuality in delivery, quality of the product, satisfaction of the customer) without investments for the purchase of fixed assets, the production trend of which is well established.

### *4.3. Relationship between Fish Farms and Support Measures*

There are two types of aquaculture farms in Italy : the traditional fish farms, which are not capital-intensive, including many extensive systems, and the innovative fish farms, which on the contrary are capital-intensive, characteristic of intensive systems.

All the interviewees expressed themselves very favourably towards a research applied to the real problems and needs of the sectors, even hoping for public-private integration.

Among the criteria which serve to describe the figure of the entrepreneur, such as risk, duties of promotion and coordination, decision-making power, what seems to be fundamental and necessary for the aquaculturist entrepreneur and for the entire sector is the definition given by Schumpeter in 1912 : « The entrepreneur is the one who introduces innovations, and this characteristic may apply to every man, apart from the position held and the time spent to reach such a position ». Since the gap existing between the Italian system and the foreign system is attributed not only to high production costs but also to an insufficient cooperation among « entrepreneurs of little initiative », for the years to come everyone hopes for an innovative entrepreneurial and managerial orientation, market-oriented, cooperating, characterized also by joint ventures and particularly sensitive to the quality of the product.

Within this aim, the setting up of family businesses may represent a factor of great success.

Every type of aquaculture is suitable for, to some extent, being carried out or introduced in family fish farms, without prejudice to the integration of the fish farms themselves into a wider production cycle, which includes reproduction and weaning centres, plants for the production of foods, services for technical assistance, etc.

The possibility of carrying out an activity of this type in the same way as a family business has therefore its positive aspects not only for agriculture near bodies of water (complementarity) but also for the fisheries sector (professional evolution of the employees). In fact, fisheries carried out at present in our country is to a great extent an activity of the inshore type, which makes use of small fishing boats and employs people with limited professional qualification, within a considerable unbalance between productive capacity (a large number of fishing boats) and actual fish output.

Furthermore, if we examine the status of those who operate for example in the lagoons of Veneto and Emilia-Romagna, we discover a not very favourable situation : labour force ageing little by little, marginal incomes, insufficient propensity to invest, etc.

The measures in credits and contributions introduced by the European Economic Community, by the Ministry of the Merchant Marine and by the regions contribute only very little to solve the problem : on the one hand, there are those

who introduce innovations thus making fisheries more productive in the short term but impoverishing the sea resources (or lagoon), on the other there are those who, in the majority, are little by little cast out and pushed back towards situations of economic marginality or part-time.

It is for these reasons that aquaculture, once its compatibility with the environment has been ascertained, can become a method of rational exploitation of wetlands and also a moment of professional qualification and social evolution of fishermen, at least for some forms of fisheries. The fisherman would be described not as user of a natural resource which is little by little becoming extinct but rather as actor of a productive process, thus also changing the traditional attitude towards water, now seen as field of action instead of reservoir. In the fish farm of the aquaculture sector the ex-fisherman becomes in this way an entrepreneur able to manage the cycle and phases of production and to put to good use his particular knowledge and sensitivity.

As far as the relationship between the age of employees and their professional qualification is concerned, it is well-known that many activities of the primary sector do not suit the younger members of the family, since those activities belong to the tradition of « unpleasant jobs » ; this should not apply to the aquaculture sector, since it offers the young people the possibility of a personal as well as a professional improvement.

The opportunity to carry out an activity which so far has been the privilege of few people in possession of this technology will be an incentive not to be underestimated in the new investment plans.

Aquaculture, as clean highly technological zootechnics, can be a winning factor if the objective is to exploit, in the form of family business, the various wetlands of our country : the development of aquaculture is not only compatible with the size and organization of the family business, but it also represents an incentive of great interest to stabilize young workers in the primary sector.

But it should be taken into account that the professional figure of the aquaculturist may originate from the specialization of the farm worker as well as from the evolution of the traditional fisherman. The latter shows positive aspects from the socioeconomic point of view, since it enables the employee to carry out a full-time professional activity.

A family management will be a good barrier against the risks for « industrial » concentration of investments and mummification of the environment, which could occur if the territory is left « natural » and if the task of preventing production fragmentation is remitted to a reform on wetlands to be hoped for.

## 5. CONCLUSIONS AND IMPLICATIONS

Every production-oriented firm has its corner-stone in two main factors : the human and the technological factor. The optimization of these two components can be realized through the identification of their initial status (start-up phase) and the continuous attention to their evolution.

The results of the analysis carried out so far have pointed out the existence of hidden or manifest potentials for the optimization of human resources and the existing technology, but also a marked lack of coordination between operating policies and structures which could realize the optimization and the synergism of the available resources.

The formation of distinctive skills which can contribute to increase the growth of the aquaculture sector in the Italian economy can be fulfilled in the pursuit of a prudent community support policy to be intended as a real basis for intervention for the Public Administration and producers' associations, in the pursuit and fulfillment of a consolidation and a continuous exchange between scientific research and firms, in the increase of relations among firms for an entrepreneurial cooperation which may give rise to a continuous transfer of knowledge and skills. The cultural changes must be accompanied by a sound and prudent investment policy, which represents the point of junction between investments in human resources (managerial operating level) and investments in technologies and structures.

We have to mention as well the need for pursuing the so-called global quality in order to improve the competitiveness of the product so as to create a factor for the protection of the national production of increasingly competitive imports.

But this does not mean that we have to neglect the pursuit of technical and economic efficiency which has to be an instrument for the attainment of sought-after objectives such as the pursuit of a better product from a qualitative point of view and the use of increasingly competitive technologies.

The short-term strategies can therefore be effectively supported by national and EEC contributions which, at the moment, lack only a clear definition of standard reference criteria to guide the choice of investments in economical farms. Such plants are intended to recover productivity according to criteria of efficiency and effectiveness in such a way so as to make the final product qualitatively and economically competitive compared to the imported product. The contributions will depend on the phase of life of the plant, in view of the final market.

It will be advisable to distinguish the outlet according to the destination of the product, considering it divided into the following segments : market of the final consumer, catering, market of the industrial processing.

Therefore, from a strategic point of view, it is necessary for entrepreneurs to switch from a production-oriented position (as suggested by factors such as crisis in the fishing sector, increase in per capita consumption, rise in imports) to a market-oriented position, or to be more exact oriented to outlets suitably divided into segments and evaluated from an economic point of view.

The achievement of these values depends on the actors of the aquaculture system, their experience acquired in the sector or elsewhere, their background and on their culture, which can make it possible to increase their skills and determine a possible cooperation among firms.

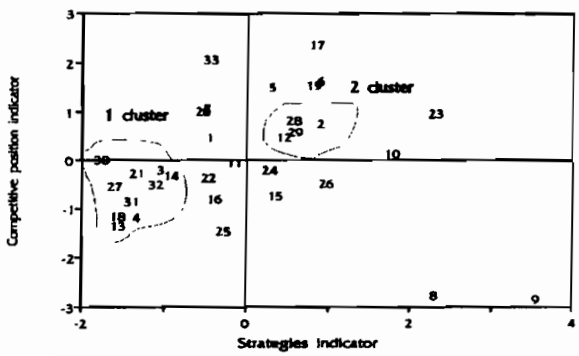
Managerial component (Fig. 4)



Relationship between interfirm relations and managerial strategies. (Fig. 5)

Hindrance to the management of a productive activity analysis. (Fig.6)

Strategies and competitive position analysis. (Fig. 7)

**SESSION 1 : FISHERIES COMMON POLICY**

**A : PLENARY SESSION**

The EEC-Common Fisheries Policy and the 1991-Report
P. Andersen ..... 15

The Fisheries Structural Policy on the Horizon of the Year "2000"
E. Mastracchio ..... 19

Définition et mise en œuvre de la Politique Commune des Pêches de la CEE : le point de vue d'un Etat membre
C. Bernet ..... 25

**B : INSTITUTIONS AND FISHERIES COMMON POLICY**

The Relationship between Fleet Capacity and Fishing Effort
G. Valatin ..... 29

The European Community Decision Making Process : Fisheries with Reference to the Role of the European Parliament
D.I.A. Steel ..... 37

The Common Fisheries Policy and the Role of Producer Organisations in South West England : Economic Considerations
J. Slaymaker, A. Hatcher and S. Cunningham ..... 45

**C : EVALUATING THE SOCIO-ECONOMIC IMPACT OF THE E.E.C. FISHERY POLICY**

Evaluating Socio-Economic Impact of EEC Fishery Policy Using a Social Accounting Matrices Approach
G. Cella, V. Placenti and M. Spagnolo ..... 53

**SESSION 2 : AQUACULTURE SECTORAL DYNAMICS**

**A : GENERAL SESSION**

A Comparative Study of the Development of Mussel Farming in Scotland and Ireland with Emphasis on the Development of Marketing
M. Gabbot, S.A. Shaw and J. Gibbs ..... 77

Economic Evaluation of the Red Sea Bream Ranching in Kagoshima, Japan
J.R. Ungson, H. Hirata and Y. Matsuda ..... 87

Adoption of Innovations in the Norwegian Aquaculture Industry - Perceived Attributes
K. Hansen ..... 97

Scandinavian Aquaculture in a Global Perspective. A Study Concerning Structural and Marketing aspects
R. Cedrins ..... 109

**B : PANEL SESSION - SALMON PRICE AND MARKET**

What is the "Right" Price of Norwegian Salmon?
R. Hannesson ..... 119

Why 1991 Alaskan Salmon Prices Crashed
M. Herrmann and J.A. Greenberg ..... 129

SESSION 3 : FISHERIES MODELLING

A : MULTI-OBJECTIVES MODELLING

Multi-Objective Programming : an Application to the Pacific Whiting (Merluccius productus) Fishery
R.R. Enriquíez and G. Sylvia ..... 145

A Multiple-Criterion Optimization Approach for the Management of a Multispecies Fishery with Ecological and Technological Interdependencies
J.C. Seijo, O. Defeo and A. de Alava ..... 161

The Role of Multiobjective Policy Models in Fisheries and Aquaculture Development
G. Sylvia ..... 171

Bioeconomic Multispecies Modelling of the Barents Sea Fisheries
A. Eide and O. Flaaten ..... 183

B : FISHERMEN BEHAVIOUR

A Bioeconomic Model for Fish Harvest Technology
D.B. Sampson ..... 197

Dynamics of Resource and Fishermen Behaviour in Coastal Invertebrate Fisheries
J.C. Seijo and O. Defeo ..... 209

C : OTHERS

Analysis of Some Management Options for a Small Pelagic Fishery in Central Philippines
J.E. Padilla and P. Copes ..... 223

The Usefulness of Bioeconomic Models under biological Uncertainty : a Case Study of the Australian Southern Shark Fishery
S. Pascoe, T. Battaglene and D. Campbell ..... 237

Simulation Model of Factory Trawler Operation
I. Arnarson and P. Jensson ..... 247

The Nordic Fisheries Management Model - Themodel and the data for the Icelandic version
A. Danielsson ..... 261

Sources of Variance in the Economic Performance of New England Otter Trawl Vessels
I.J. Anwar, P. Lallemand and J. M. Gates ..... 273

A General Bioeconomic Simulation Model ofthe catching Sector of a Multispecies Fishery
P. Rodgers ..... 283

BEAM 4 - A Bio-Economic Model for the Simulation of Space-Structured Multi-Species and Multi-fleet Fisheries
P. Sparre and R. Willmann ..... 293

Gérez Vos Pêcheries
C. de Verdelhan ..... 305

**SESSION 4 : AQUACULTURE ENTERPRISE MANAGEMENT**

**A : GENERAL SESSION**

Profitability of Catfish on a Representative Multiple Enterprise Farm in the Southeastern United States Under Conditions of Risk
R.S. Pomeroy, S.M. Carlier and C.E. Curtis ..... 315

The Management Schemes for Brackishwater Pond Production
Mudiantono ..... 331

Dynamic Cash Flow Models in Aquaculture: Amplifying the Scope of Managers
C.S. Wright ..... 343

**B : PANEL SESSION**

Elaboration d'un modèle bio-économique dynamique relatif à l'élevage de la palourde de l'Atlantique *(Spisula solidissima)*
M. Martin, J.R. Wilson, L. Adambounou and R. Bouchard ..... 355

A Model for the Optimal Management of Sea-Bass Aquaculture
G.F. Rizzo and M. Spagnolo ..... 367

Simulation of Aquaculture Production for Economical and Environmental Impact
M. Spratt ..... 401

**SESSION 5 : CONSUMPTION AND DEMAND**

**A : CONSUMPTION AND DEMAND**

Consumer Ability to Discern Seafood Quality : Results of Experimental Studies
J.G. Anderson, C.R. Wessels ..... 417

Conjoint Analysis of the Japanese Salmon Market
Y. Kusakabe and J.L. Anderson ..... 427

Seafood Consumption and Giffen Behavior
R.S. Johnston and D.M. Larson ..... 437

The Changes Affecting the Demand for Fish and Fishery Products in Poland
A. Gwiazda ..... 449

Testing the Consistency of Fish Consumption Data with Neo-Classical Demand Theory
M. Burton and T. Young ..... 457

**B : FOOD SAFETY**

The Northeast United States Market for Blue Mussels : Consumer Perceptions of Seafood Safety and the Demand for Mussels
P.M. Brooks and J.L. Anderson ..... 463

Seafood Safety Assurances : Implications for Seafood Marketing and International Trade
C.R. Wessels and J.G. Anderson ..... 475

**SESSION 6 : INTERNATIONAL EXCHANGES**

**A : INTERNATIONAL TRADE POLICY AND COMPETITION**

Development of the International Trade in Seafood Products in the Context of European Economic Integration
J.P. Boule and P. Guillotreau ..... 485

U.S. Demand for and Canadian Supply of Fish Products
R.L. Mazany, N. Roy and W.E. Schrank ..... 501

Price Fluctuation and Substitution in the Groundfish Market
T. Trondsen ..... 517

The Icelandic Cod Trade : An Econometrically Based Simulation Model
R. Arnason and T. Felixson ..... 531

An Approach to the Management of Market and Resource Uncertainties : The Globalisation of Trade Information
J.-F. Mittaine ..... 555

The Market Outlook for Shrimp
M.-C. Yang ..... 561

Changes in Poland's Foreign Trade Management and Impacts on the Foreign Trade of Fishery Products
H. Nakonieczna-Kiesiel and J. Zieziula ..... 573

Le commerce extérieur français des produits de la mer en 1991
J. Dari ..... 581

Monopsony, Trade Restrictions and International Markets for Intermediate Seafood Products : The U.S.-Canada Herring Dispute
A. Emami, L.E. Queirolo and R. Johnston ..... 589

Price Linkages between Japanese and United States Markets for Sablefish and Thornyheads
J.D. Hastie, D. Squires and J.A. Elston ..... 599

The Alaskan King Crab Industry - An Industry in Transition
J.A. Greenberg, S.C. Matulich and M. Herrmann ..... 609

Java Sea purse seiners : the impact of innovation on performance
J.K. McElroy and Wijoprono ..... 617

**SESSION 7 : FISHING ENTERPRISE MANAGEMENT**

**A : ACADEMIC**

Coastal State Fisheries Management : Fleet Development Versus Trade in Fisheries Services
S. Cunningham and D. Whitmarsh ..... 639

La théorie économique de l'investissement dans le rétablissement des ressources naturelles renouvelables, avec référence spéciale au cas de la pêche du pétoncle géant aux Iles-de-la-Madeleine, Québec (Canada)
J.R. Wilson, F. Mendez and M. Fréchette ..... 647

Fishermen's Time Discounting Rates and other Factors to be Considered in Planning the Rehabilitation of Depleted Fisheries
J.P. Hillis and B.J. Whelan ..... 657

Hysteresis et comportements adaptatifs des pêcheurs artisanaux
H. Rey ..... 671

Prediction of Financial Distress in the Norwegian Fish Processing Industry
B. Dreyer and T. Vassdal ..... 683

**B : FISHING ENTERPRISE MANGEMENT**

Unemployment Insurance and the Length of the Fishing Season
N. Roy, E. Tsoa, W.E. Schrank and L. Mazany ..... 693

Multiproduct Tuna Fisheries in the South WestPacific
H.F. Campbell, A. McIlgorm and R.B. Nicholl ..... 715

Portfolio Selection in Fishing Strategies in a Multispecies Trawl Fishery
S. Hanna ..... 727

Un essai d'identification des stratégies de pêches : le cas de la pêche artisanale dans le nord de la France
F. Lantz, M.-O. Allard and R. Junaueir-Lopez ..... 745

The effect of government subsidies on the formation of collusions in an oligopolistic fishery
P. Mickwitz and M. Hildén ..... 759

Productivity Measurement in Common Property Resource Industries : an Application to the Pacific Coast Trawl Fishery
D. Squires ..... 769

**SESSION 8 : FISHING REGULATORY TOOLS**

Fundamental Issues in the Design of ITQ Programs
L.G. Anderson ..... 787

Marketing Losses in Regulated Open Access Fisheries
J.E. Wilen and F.R. Homans ..... 795

The Role of Economics in the Development of Limited Entry Programs : Two Examples from Groundfish Fisheries in the Western United States
J.D. Hastie ..... 803

Exvessel Price Behavior in West Coast U.S. Groundfish : Implications for the Choice of Fishery Management Technique
S. Hanna ..... 813

Multiproduct Supply under Production Quota : an Application to Pacific Fisheries
D. Squires ..... 827

The potential Benefits of Individual Transferable Quotas and their Effects on Industry Structure
D. Squires ..... 839

Productivity and Efficiency of the Fishing Fleet : the Case of the Small Scale Fishing Enterprises in Boulogne
C. Ioannidis and F. Lantz ..... 851

Setting Total Allowable Catches based on Market Conditions : Economics of Atlantic Herring Roe Production
R. Nowak ..... 859

Fisheries Regulation and the Incentives to Overfish
R.L. Mazany, A.T. Charles and M.L. Cross ..... 873

Fixed or Variable Catch Quotas with Irreversible Investments
S.I. Steinshamm ..... 881

Renewable Resource Market Obeying Difference Equations : Stable Points, Stable Cycles, and Chaos
C.C. Duarte ..... 891

Individual Fishing Rights : Some Implications of Transferability
P. Copes ..... 907

Considerations for an Individual Transferable Quota Program for the South Atlantic Mackerel Fishery
K.F. Wellman, J.W. Milon and J. Gauvin ..... 917

From Open Access to Communal Property : the Case of the Fishing Community in Muxía.
A.G. Allut ..... 929

Impact of Product Mix on Optimal Fishing Quota
I. Arnarson and P. Jensson ..... 937

**SESSION 9 : DISTRIBUTION AND PROCESSING**

UK Fish Processing Industry Strategies: From the CFP Decade to the Single Market
J.A. Young and J.F. Muir ..... 955

Stratégies des industries de transformation et approvisionnement en produits halieutiques : le cas du Sénégal
M. Dème and M. Bakhayokho ..... 971

Stratégies technologiques dans les industries de transformation
L. Temri ..... 979

Consumption of Seafood, Poultry and Meat in Restaurants vs. Supermarkets
T. Naito, R.S. Johnston and A.L. Shriver ..... 989

Cross-Hedging Fishmeal with Soybean Meal Futures
T. Vukina and J.L. Anderson ..... 1001

Market Analysis Institutional Behaviour and Marketing of Fish in Portugal
S. Cruz ..... 1015

Monopolistic Aspects of Word Trade of Fishing Industries in Portugal
S. Cruz ..... 1029

**SESSION 10 : MARKET, PRICE AND PRODUCTION SYSTEMS**

**A : GENERAL SESSION**

Market Structure and Prices : the Marseille Fish Market
A. Kirman ..... 1051

Relative Price Variability in Fisheries some Policy Implications
C. Ioannidis ..... 1059

The Market Interaction of Wild Salmon Fisheries and Salmon Aquaculture
C.S. Wright and P. Copes ..... 1071

Determinants of Price in the Portland, Maine Fish Auction
N. Ty and J.M. Gates ..... 1093

The Price Equalization Fund of the Fisheries in Iceland A Descriptive Study
O.Ö. Klemensson ..... 1105

**B : MARKET ORGANIZATION AND FISHERIES STATISTICS IN JAPAN**

Fish Marketing System Developed in Japan and Price Maintenance Mechanism
K. Miki and T. Yamamoto ..... 1115

Fishery Cooperative Association in Japan and its Vital Role in Fish Marketing
N. Odaka and T. Yamamoto ..... 1125

Supply and Demand of Fish and Fisheries Products in Japan
G. Bourguignon ..... 1131

Dual Structure of Japanese Marine Fisheries and Role of Fisheries Statistics in Fisheries Administration
T. Yamamoto ..... 1143

**SESSION 11 : RESOURCES VALUE AND CONFLICTS**

**A : RESOURCE VALUATION AND CONFLICTS**

On Inferior Goods and Giffen Effects in Recreation Demand Analysis
D.M. Larson and R.S. Johnston ..... 1163

International Issues in Valuation of Commercial and Recreational Fisheries
R.S. Johnston and A. Emami ..... 1175

Production Domestique, Absence de Marchés et Marchés Manquants dans les Economies en Développement : Analyse d'Impact de Projet dans le Secteur des Pêches
P. Failler and J.R. Wilson ..... 1189

Commercial Fisheries and Sport Fishing: Conflict and Cooperation
T. Kusakawa ..... 1201

Subsistence Fisheries in Alaska : Conflicts Within a Multiple Use Resource
H.T. Geier, J.A. Greenberg and M. Herrmann ..... 1213

**B : INFORMATION**

Information Needs and the Management of Joint Commercial and Recreational Fisheries : the UK Fishery for Sea Bass (*DicentrarchusLabrax*)
S. Potten, M. Dunn and D. Whitmarsh ..... 1223

The New Institutional Economics (NIE) Applied to the Fisheries : the Role of Information in the (Continuing) Solution of Resource Problems
J.R. Wilson and R. Lent ..... 1233

Cooperative Fishing Arrangements between Coastal Countries and Distant Water Fleets
L.E. Queirolo and R.S. Johnston ..... 1249

La comptabilité des ressources naturelles: une application aux ressources salmonicoles
A. Webster ..... 1259

**SESSION 12 : FISHING AND DEVELOPMENT**

Quelle Place pour les Pêches Africaines dans le Cadre de la Nouvelle Donne Mondiale ?
S.C. Nana Sinkam ..... 1273

Problématiques du Développement des Pêches
J. Weber ..... 1293

La Pêcherie de Crabe des Neiges au Canada en tant que Système : Variables, Interactions et Incertitudes
J.C. Brêthes and R. Dufour ..... 1301

Development and Diversification : Sustainability Strategies for a Costa Rican Fishing Cooperative
A.T. Charles and A. Herrera ..... 1315

Structure, Constraints and Development Options of Fish Processing and Marketing in Namibia
R. Lasch ..... 1325

The Welfare Impact of Improved Boat Modernisation Schemes (IBMS) in Pemalang Regency, Central Java - Indonesia
I. Susilowati ..... 1337

The Establishment of Chinese Marine Fisheries Laws and their Management Practice
Z. Guanghua ..... 1351

Évaluation de l'Impact de la Flotte des Pays de la CEE dans l'Économie du Sénégal
M. Kébé ..... 1357

**SESSION POSTER**

Bioeconomic Considerations regarding the Opening of a Autumn Fishery on Capelin in 1991
P. Sandberg and P. Gullestad ..... 1367

"Sevryka" - A new Competitor in the European Seafood Market ?
F. Nilssen ..... 1371

Contraintes Économiques et Sociales et Développement de l'Aquaculture extensive et diversifiée dans un Pays en Voie de Développement. "Le Cas de la Côte orientale de Madagascar"
G. Rafomanana ..... 1381

Canadian Household Demand for Protein : a Lifecycle Approach
D.J. DeVoretz and K.G. Salvanes ..... 1391

La pêcherie artisanale maritime des filets dormants à sole (*cynoglossus sp.*) en Casamance (Sénégal)
H.D. Diadhiou ..... 1405

Skipjack Pole and Line Fishing in EastIndonesia
J.K. McElroy and J.C.B. Uktolseja ..... 1417

Production planning and the managerial behaviour of the fish-farm entrepreneur in Italy
C. Iandoli, E. Alaio, R. Bianco and G. Vito ..... 1431
