Casilla de Correos 122, 5000 Córdoba, Argentina,
and *** Universiteit Gent, Instituut voor Dierkunde, Ledeganckstraat 35, 9000 Gent, Belgium.

Accepted for publication 20 November 1997.

Summary – *Paraxiphidorus brevistylus* sp.n. is described based on male, female, and juvenile specimens from uncultivated soil in Argentina. The new species is characterized by the short odontostyle, the comparatively anterior position of the guide ring, and a combination of body length, lip region width, and number of ventromedian supplements similar to those of *P. michelluci* and ratios a and c, spicule length, and length of lateral guiding pieces similar to those of *P. heynsi*. Additional information is provided on *Xiphidorus minor*, *Xiphinema surinamense*, and *X. krugi*. The reproductive system (structure of the uterus) of Argentinean females of *X. surinamense* was somewhat different from earlier descriptions: in the posterior branch, the proximal part of the uterus is well differentiated from a narrower strongly developed muscular median uterus filled with spiniform crystalloid structures; in the anterior branch, the uterus is long, glandular, and not clearly differentiated. © Orstom/Elsevier, Paris

Résumé – *Longidoridae provenant d'Argentine avec description de Paraxiphidorus brevistylus sp. n. (Nematoda: Longidoridae)* – *Paraxiphidorus brevistylus* sp.n. est décrit sur des spécimens mâles, femelles et juvéniles provenant de sol non cultivé d'Argentine. Cette nouvelle espèce est caractérisée par un odontostyle court, un guide du stylet en position comparativement antérieure et une combinaison de caractères similaire à celle de *P. michelluci* : longeur du corps, largeur de la région labiale et nombre de suppléments medioventraux ; elle présente également des caractères rappelant *P. heynsi* : rapports a et c, longueur des spicules et des pièces latérales du gubernaculum. Des données nouvelles sont apportées sur *Xiphidorus minor*, *Xiphinema surinamense* et *X. krugi*. Les caractères de l'appareil reproducteur femelle de *X. surinamense* d'Argentine diffèrent quelque peu de ceux précédemment décrits par la partie proximale de l'utérus bien séparée de la partie médiane étroite, très musculeuse et contenant des structures cristaloïdes spiniformes, ainsi que par l'utérus antérieur long, glandulaire et à peine différencié. © Orstom/Elsevier, Paris

Keywords: Argentina, Longidoridae, nematodes, *Paraxiphidorus*, *Xiphidorus*, *Xiphinema*, Xiphidorini.

An extensive survey of longidorids in Argentina (Luc & Doucet, 1990) resulted in the collection of numerous populations pertaining to various species of *Xiphidorus*: *X. achalae* Luc & Doucet, 1984; *X. balcarceanus* Chaves & Coomans, 1984; *X. saladiensis* Chaves & Coomans, 1984; *X. yepesara yepesara* Monteiro, 1976; *X. yepesara parthenus* Monteiro, Lordello & Nakasono, 1981; and an unnamed species close to *X. achalae*. *X. amazonensis* Uesugi, Huang & Cares, 1985 was recorded later (Decraemer *et al.*, 1996). During recent field trips, several populations of *X. balcarceanus* and one population of *X. minor* Rashid, Coomans & Sharma, 1986 were recorded as well as a new species of *Paraxiphidorus* Coomans & Chaves, 1995, the other genus of the Xiphidorini. *Paraxiphidorus brevistylus* n.sp., the third species described in this genus, was found in association with *Xiphidorus balcarceanus* and *Xiphinema surinamense* Loof & Maas, 1972. The association of two species belonging to the two genera of the Xiphidorini con-

firms the observations made by Coomans *et al.* (1996) and their remark on Xiphidorini being less rare than previously thought. Additional data were collected on the variability of morphometric features and on the variation of uterus structure in *X. surinamense*. These observations led to some comments on the relationships of this species with *X. krugi* Lordello, 1955. Argentinean populations of the latter species were also studied.

The populations of the *Xiphidorus*, *Paraxiphidorus* and *Xiphinema* species studied were the following:

Pop. 1: Pampa de Achala, San Alberto Department, Córdoba Province; rhizosphere of grasses on sandy soil.

Pop. 2: Estancia Los Condoritos, San Alberto Department, Córdoba Province; rhizosphere of grasses on sandy soil.

Pop. 3: Los Gigantes, Punilla Department, Córdoba Province; rhizosphere of grasses.

Pop. 4: Cerro Hermoso; Pampa de Achala, San Alberto Department, Córdoba Province; rhizosphere of grasses on sandy soil.

Pop. 5: San Clemente, Calamuchita Department, Córdoba Province; rhizosphere of grasses.

Pop. 6: Malena, Rio Cuarto Department, Córdoba Province; rhizosphere of soybean.

Pop. 7: Marcos Juarez, Marcos Juarez Department, Córdoba Province; habitat unknown.

Pop. 8: Parque Nacional 'El Palmar', Colón Department, Entre Ríos Province; rhizosphere of grasses.

Pop. 9: El Manzano, Colón Department, Córdoba Province; rhizosphere of *Morus alba*.

The specimens were extracted from the soil by centrifugation-flotation, fixed with 4% formalin, and mounted in pure glycerine using a modified Seinhorst (1959) method. Drawings were made using a Reichert Polyvar light microscope.

Type material of *X. surinamense*, *Paraphididorus michelluci*, and *P. heynsi* Coomans, Chaves & De Leon, 1996 was also studied.

Paraphididorus brevistylus sp.n.

(Figs 1, 2)

MEASUREMENTS

See Table 1

DESCRIPTION

Male*: Body long and rather slender, spiral upon fixation, with posterior part more ventrally curved than in female. Cuticle 3 µm thick at neck region and mid-body and 14 µm (holotype) thick at tail tip, with three main layers and with fine transverse striations well defined in the tail region. Lateral chord 4.5 µm at level of cardia, 19 µm wide at mid-body or 26% of the corresponding body width in holotype. Numerous lateral body pores present along the body (twenty in neck region of holotype) but few pores present dorsally and ventrally. Dorsal pores present only in odontostyle region (five, holotype) and ventral pores only in neck region (nine, holotype). Lip region hemispherical to slightly flattened anteriorly, offset by marked constriction. Body cuticle behind constriction bulging outward (3.5 µm thick) due to a thickening of the median layer. Anterior sensilla arranged into inner and outer circles with six and ten sensilla, respectively. Amphids with stirrup-shaped fovea and slit-like opening 10.5 µm wide or 78% (holotype) of head width at constriction. Odontostyle long and slender, with forked base; odontophore with weakly developed flanges, 6-8 µm wide; pharyngeal retractors weakly developed. Guide ring single, posteriorly located. Vestig-

ium present at 73 µm from base of odontophore in holotype and in a male paratype. Pharyngeal bulb not sharply offset from slender part of pharynx; dorsal gland nucleus smaller than both ventrosublateral nuclei. Positions of outlets and nuclei as percentages of bulb length in holotype: DO = 6.5, DN = 31, RSN = 48.5, LSN = 50, and SO = 60. Pharyngo-intestinal junction wide and flattened with rather obscure conoid central valve. Anterior part of intestine with three to four cells in circumference. Prerectum 1.5 to twice as long as the region of copulatory muscles. Reproductive system typical for the genus, entirely contained in the posterior half of the body or slightly longer; sperm 7 × 3.5 µm. Each side of the reproductive system includes four to five ejaculatory glands and 42-46 copulatory muscles extending to a level slightly anterior to the anteriormost supplement. Four (one paratype) or five caudal copulatory muscles present. In some specimens, two cloacal muscles observed between the spicules, and two rectal glands present dorsally from cloaca. Six or eight (in one paratype) equally developed ventro-median supplements present, in addition to the paired genital papilla opposite the posterior third of retracted spicules. Spicules stout, curved ventrad; lateral guiding pieces rod-shaped. Tail dorsally convex-conoid with broadly rounded terminus and slightly concave ventral side, without blind canal; two to three caudal pores on each side, one pore around opposite cloacal opening. Seven to nine subventral body pores in the region of the copulatory muscles.

Female: Similar to males in most respects except for sexual characteristics. Posterior part of body less strongly curved ventrad. Cuticle 3-3.5 µm thick at level of cardia, 3.7-4 µm at mid-body, 14-15.5 µm at tail tip. Lateral chord 19-22 µm wide or 30.5-34% of corresponding body diameter at mid-body. Neck with 4-5 dorsal, 8-11 ventral, and 17-22 lateral pores (n = 2). Vestigium 54-87 µm posterior to base of odontophore. Tail dorsally convex-conoid with broadly rounded terminus without blind canal; two caudal pores present on each side. Reproductive system didelphic-amphidelphic; both branches about equally developed. Uterus without *pars dilatata*; proximal parts of both uteri forming a poorly developed ovejector; sperm present in some cases throughout the uterus, stored in the *pars dilatata oviductus* (= functional spermatheca). Vagina 39-43 µm or 60-72% of corresponding body diameter.

Second stage juvenile: General body shape similar to females. Cuticle 2 µm at mid-body, 9 µm at tail tip; lateral chord 9.5 µm wide or 25% of mid-body width. Tip of the replacement odontostyle 20 µm posterior to base of odontophore. Genital primordium 28 µm long. Tail dorsally convex-conoid, slightly longer than

* The indication of a male specimen as holotype, an uncommon procedure in the description of longidorids, is justified by the type species of the genus with female unknown.

one anal diameter, i.e., clearly longer than tails of adults.

Third stage juveniles: General body shape similar to females. Cuticle 2.5-3 µm at mid-body, 10.5-12 µm at tail tip; lateral chord 15-17.5 µm or 28-29.5 % of mid-body width. Tip of the replacement odontostyle 4.5-26 µm posterior to base of odontophore. Tail as in females. Genital primordium 45-66 µm long; the more developed ones showing the beginning of a differentiation in two branches.

DIFFERENTIAL DIAGNOSIS

Paraxiphidorus brevistylus sp.n. differs from the other two species of the genus – *P. michelluci* Coomans &

Chaves, 1995 and *P. heynsi* Coomans, Chaves & De Léon, 1996 – by the shorter odontostyle and the anterior position of the guide ring in males. It further differs from *P. michelluci* by longer spicules and lateral guiding pieces, and from *P. heynsi* by a narrower lip region and lower number of supplements (see Table 2).

TYPE LOCALITY AND HABITAT

Pampa de Achala, San Alberto Department, Córdoba Province, Argentina (Pop. 1); rhizosphere of grasses on sandy soil; associated with *Xiphidorus balcarceanus* and *Xiphinema surinamense*.

TYPE SPECIMENS

Male holotype (slide RAC 105), one paratype female (slide RAC 106), one J3 (slide RAC 107), and one J2 (slide RAC 108) in the Collection of the Centro de Zoología Aplicada, Universidad nacional de Córdoba. One male paratype (slide RIT 556), one female paratype (slide RIT 557), and one J3 (slide RIT 558) in the Collection of the Royal Belgian Institute of Natural Sciences, Brussels. One male paratype (slide RUG 2946) and one female paratype (slide RUG 2947) in the Collection of the Instituut voor Dierkunde, Universiteit Gent, Belgium.

Xiphidorus minor Rashid, Coomans & Sharma, 1986 (Fig. 3)

MEASUREMENTS

See Table 3.

OBSERVATIONS

Six females and one juvenile (Pop. 9) were studied. The females agree with the original description and type material in all morphological characteristics. Their morphometric data, specifically body length and stylet length, are closer to the specimens from Uruguay (Coomans et al., 1996) (Table 3). The uteri are always short and, except in one specimen, the anterior branch is slightly longer than the posterior one. The juvenile specimen is probably in the preadult stage, based on body length, stylet length, and replacement odontostyle as long as odontostyle in female, although its genital primordium is poorly developed (24 µm long) and without differentiation into two branches or into different components.

Xiphinema surinamense Loof & Maas, 1972 (Fig. 4)

MEASUREMENTS

OBSERVATIONS

The specimens from different populations from Argentina (Pops 1-5) roughly conform to earlier descriptions in morphometric data and in general morphology (Loof & Maas, 1972; Loof & Sharma, 1979; Ferraz, 1980; Luc & Coomans, 1992), and it is thus unnecessary to give a complete redescription of this species. Some variations in morphometric data have been observed, which further enhance the large published intraspecific variability of *X. surinamense*. The lower range of the c-value is extended: c = 55.9-79 (males), c = 65.7-94.5 (females) vs c = 63-104 (males), c = 67-114 (females), as well as the lower range of V, due to a more anterior position of the vulva (in specimens from four out of five populations): V = 32.3-36.4 vs 36-45; males have longer and more slender spicules: 77-92 vs 48-75 μm , longer accessory pieces: 15-20 vs 12-14 μm , and a larger number of single ventromedian supplements varying from four to six vs one to four in earlier descriptions of *X. surinamense*.

The structure of the uteri is somewhat different from earlier descriptions. In the posterior genital branch of the Argentinean females studied, the ovejector (the proximal part of the uterus) is quite distinct from a more or less equally long but narrower, strongly developed muscular median uterus filled with refractive spiniform cristalloid structures. This muscular uterus is demarcated from the glandular distal uterus, which is as long or (usually) shorter than the proximal part. Sperm cells were observed in females of four of the five populations, located in a somewhat inflated proximal part of the narrow oviduct. In the anterior branch, the ovejector is not clearly demar-

cated from the long glandular uterus; the sphincter is less developed than the sphincter of the posterior branch, the oviduct is vestigial, and there is no ovary (Fig. 3B, C).

Previous descriptions of *X. surinamense* mentioned a posterior uterus with a weak or distinct very short muscular part adjacent to ovejector and a short glandular distal part, the anterior uterus being equally developed or longer but similar in structure (Loof & Maas, 1972; Luc & Coomans, 1992). The present study of a female paratype confirms the observations made by Luc and Coomans (1992) on a female specimen from French Guyana, but showed a somewhat longer muscular uterine part in both branches, with some granulation/gravel at this level in the posterior branch (Fig. 4A).

REMARKS

X. surinamense most closely resembles *X. krugi* but is differentiated from this species by a much longer female anterior genital branch with the uterus equally long and of the same structure as the posterior uterus. This results in a usually more posterior position of vulva in *X. surinamense* than in *X. krugi* (V = 32-45 vs. 29-36). With the current extension of the lower range of V in *X. surinamense*, this feature is no longer a reliable diagnostic character (see overlap of data). Other differences include, e.g., the abundance of males in *X. surinamense* (Luc & Hunt, 1978) and shape and length of tail. However, tail shape is a highly variable feature in *X. krugi* (tail with rounded tip or provided with a digitate process).

The main differentiating characteristic between the two species is the structure of the female genital sys-

tem with a non-differentiated posterior uterus, except for a very short enlarged distal part, and a much shorter anterior genital branch in *X. krugi*. Furthermore, the tail end in *X. surinamense* has no blind canal, whereas this structure is present in *X. krugi*.

Xiphinema krugi Lordello, 1955 (Fig. 5)

MEASUREMENTS

See Table 6.

OBSERVATIONS

Females of *X. krugi* were found in several samples from Córdoba Province (Pops 5-7) and in one sample from Entre Ríos Province (Pop. 8). They agree with earlier descriptions and show obvious between-population variation in tail shape, from almost regularly ogival with a very slight bulge at its extremity to conoid rounded with a distinct peg, as described by Luc and Hunt (1978). The specimens of Pop. 8 have

low total spear length, which slightly extends the lower limit of the range of values from 154 µm (Brazilian Pop. 3 in Luc & Hunt, 1978) to 151 µm.

Acknowledgements

The authors thank the Consejo de Investigaciones Científicas y Tecnológicas de la Provincia de Córdoba from Argentina (CONICOR) for financial support for this work (grant N° 3984, Res. 1416/97) and the Fundación for providing the installations of the 'Estancia El Condorita' for the study of soil nematodes.
